\textbf{HiVeA User Documentation}

Version 1.99

Luc Maranget*

August 30, 2012

\textbf{Abstract}

\texttt{HiVeA} is a \texttt{\LaTeX} to \texttt{html} translator. The input language is a fairly complete subset of \texttt{\LaTeX} 2e (old \texttt{\LaTeX} style is also accepted) and the output language is \texttt{html} that is (hopefully) correct with respect to version 4.0 transitional.

Recent versions of most browsers offer support for Unicode (ISO 10646) characters, albeit to different extents. \texttt{HiVeA} exploits this fact to translate various math symbols used in \texttt{\LaTeX}. As a result, almost the entire set of math symbols, including the \texttt{amsmath} ones, are correctly rendered. The use of the symbol font browsers is no longer the default.

\texttt{HiVeA} understands \texttt{\LaTeX} macro definitions. Simple user style files are understood with little or no modifications. Furthermore, \texttt{HiVeA} customization is done by writing \texttt{\LaTeX} code.

\texttt{HiVeA} is written in Objective Caml, as many lexers. It is quite fast and flexible. Using \texttt{HiVeA} it is possible to translate large documents such as manuals, books, etc. very quickly. All documents are translated as one single \texttt{html} file. Then, the output file can be cut into smaller files, using the companion program \texttt{HiCopa}.

\texttt{HiVeA} can also be instructed to output plain text or info files.

Information on \texttt{HiVeA} is available at \url{http://hievea.inria.fr/}.

Part A

Tutorial

1 How to get started

Assume that you have a file, a .tex, written in \LaTeX, using the article, book or report style. Then, translation is achieved by issuing the command:

`# hevea a.tex`

Probably, you will get some warnings. If \Hevea does not crash, just ignore them for the moment (Section 4 explains how to correct errors).

If everything goes fine, this will produce a new file, a .html, which you can visualize through a HTML browser.

If you wish to experiment \Hevea on small \LaTeX source fragments, then launch \Hevea without arguments. \Hevea will read its standard input and print the translation on its standard output. For instance:

`# hevea`

```
$> \texttt{\$\$ > /mathcal\{E\}$}
^D
<\texttt{\$\$ > /mathcal\{\texttt{E}\}$>
```

Incidentally, notice that the symbol “£” translates to the appropriate numerical character reference and that the calligraphic letter “£” renders as a red “E”. You can find some more elaborate examples\footnote{\url{http://hevea.inria.fr/examples/index.html}} in the on-line documentation.

2 Style files

\LaTeX style files are files that are not intended to produce output, but define document layout parameters, commands, environments, etc.

2.1 Standard base styles

The base style of a \LaTeX document is the argument to the \texttt{\documentclass} command (\texttt{\documentstyle} in old style). Normally, the base style of a document defines the structure and appearance of the whole document. \Hevea really knows about two \LaTeX base styles, article and book. Additionally, the report base style is recognized and considered equivalent to book and the seminar base style for making slides is recognized and implemented by small additions on the article style.

Base style \texttt{style} is implemented by an \Hevea specific style file \texttt{style.hva}. More precisely, \Hevea interprets \texttt{\documentclass(style)} by attempting to load the file \texttt{style.hva} (see section C.1.1.1 on where \Hevea searches for files). Thus, at the moment, \Hevea distribution includes the files, \texttt{article.hva}, \texttt{book.hva}, etc.

2.2 Other base styles

Documents whose base style is not recognized by \Hevea can be processed when the unknown base style is a derivation of a recognized base style.

Let us assume that \texttt{doc.tex} uses an exotic base style such as acmconf. Then, typing \texttt{hevea doc.tex} will yield an error, since \Hevea cannot find the acmconf.hva file:
This situation is avoided by invoking \HVA with the known base style file \texttt{article.hva} as an extra argument:

\begin{verbatim}
# hevea article.hva doc.tex
\end{verbatim}

The extra argument instructs \HVA to load its \texttt{article.hva} style file before processing \texttt{doc.tex}. It will then ignore the document base style specified by \texttt{\documentclass} (or \texttt{\documentstyle}).

Observe that the fix above works because the \texttt{acmconf} and \texttt{article} base styles look the same to the document (i.e. they define the same macros). More generally, most base styles that are neither \texttt{article} nor \texttt{book} are in fact variations on either two of them. However, such styles usually provides extra macros. If users documents use these macros, then users should also instruct \HVA about them (see section 4.1).

Finally, it is important to notice that renaming a base style file \texttt{style.cls} into \texttt{style.hva} will not work in general. As a matter of fact, base style files are \TeX and not \LaTeX source and \HVA will almost surely fail on \TeX-\ish input.

### 2.3 Other style files

A \LaTeX document usually loads additional style files, by using the commands \texttt{\input} or \texttt{\usepackage} or \texttt{\input}.

#### 2.3.1 Files loaded with \texttt{\input}

Just like \LaTeX, \HVA reacts to the construct \texttt{\input\{file\}} by loading the file \texttt{file}. (If I got it right, \HVA even follows \TeX's crazy conventions on .tex extensions).

As it is often the case, assume that the document \texttt{doc.tex} has a \texttt{\input\{macros.tex\}} instruction in its preamble, where \texttt{macros.tex} gathers custom definitions. Hopefully, only a few macros give rise to trouble: macros that performs fine typesetings or \TeXish macros. Such macros need to be rewritten, using basic \LaTeX constructs (section 4 gives examples of macro-rewriting). The new definitions are best collected in a style file, \texttt{macros.hva} for instance. Then, \texttt{doc.tex} is to be translated by issuing the command:

\begin{verbatim}
# hevea macros.hva doc.tex
\end{verbatim}

The file \texttt{macros.hva} is processed before \texttt{doc.tex} (and thus before \texttt{macros.tex}). As a consequence of \HVA behavior with respect to definition and redefinition (see section B.8.1), the macro definitions in \texttt{macros.hva} take precedence over the ones in \texttt{macros.tex}, provided the document original definitions (the ones in \texttt{macros.tex}) are performed by \texttt{\newcommand} (or \texttt{\newenvironment}).

Another situation is when \HVA fails to process a whole style file. Usually, this means that \HVA crashes on that style file. The basic idea is then to write a \texttt{macros.hva} style file that contains alternative definitions for all the commands defined in \texttt{macros.sty}. Then, \HVA should be instructed to load \texttt{macros.hva} and not to load \texttt{macros.tex}. This is done by invoking \texttt{hevea} as follows:

\begin{verbatim}
# hevea macros.hva -e macros.tex doc.tex
\end{verbatim}

Of course, \texttt{macros.hva} must now contain replacements for all the useful macros of \texttt{macros.tex}.

#### 2.3.2 Files loaded with \texttt{\usepackage}

As far as I know, \LaTeX reacts to the construct \texttt{\usepackage\{name\}} by loading the file \texttt{name.sty}. \HVA reacts in a similar, but different, manner, by loading the file \texttt{name.hva}.
H \textTeX\ distributions already includes quite a few \textTeX\ implementations of famous packages (see section B.17). When a given package (say \texttt{zorglub}) is not implemented, the situation may not be as bad as it may seem first. Hopefully, you are only using a few commands from package \texttt{zorglub}, and you feel confident enough to implement them yourself. Then, it suffices to put your definitions in file \texttt{zorglub.hva} and \textTeX\ will react to \texttt{\usepackage{zorglub}} by loading \texttt{zorglub.hva}.

See section B.5.2 for the full story on \texttt{\usepackage}.

3 A note on style

3.1 Spacing, Paragraphs

Sequence of spaces normally are translated into one single space. Newlines in the input document undergo a special treatment. A newline triggers a special scanning mode that reads all following spaces and newlines. In case at least one additional newline character is read, then \textTeX\ executes the \texttt{\par} command. Otherwise, \textTeX\ outputs a single newline character. This process approximates \textTeX\ process for introducing paragraph breaks and, as a result, empty lines produce paragraph breaks.

Space after commands with no argument is skipped (as in \textTeX) — however this is not true in math mode, as explained in section 3.2.1.

The following two subsections describe management of paragraphs and spaces after command sequences in greater detail. They can be skipped in first reading.

3.1.1 Spurious Paragraphs

Paragraphs are rendered by the means of \texttt{P} elements. \textTeX\ is a bit simplistic in breaking paragraphs and spurious paragraphs may be present in the final \texttt{HTML} document. Normally, as \textTeX\ never outputs \texttt{P} elements whose contents is made of spaces only, this should not happen very often. Unfortunately, some commands do not produce any output in \textTeX, while they do produce output in \textTeX: these commands are \texttt{\label}, \texttt{\index} etc. \textTeX\ translates \texttt{\label\{name\}} into the anchor \texttt{\textless A NAME="name"\textgreater}. As a result, the following source fragment will introduce a spurious paragraph.

This a first paragraph.

\texttt{\label\{label\}}

This is another paragraph.

Indeed, we have the following translation:

\texttt{\textless P \textgreater This a first paragraph.\textless /P\textgreater}
\texttt{\textless P \textgreater \textless A NAME="label"\textgreater \textless /A\textgreater \textless /P\textgreater}
\texttt{\textless P \textgreater This is another paragraph.\textless /P\textgreater}

Most of the time, such extra paragraphs remain unnoticed. Of course, they can be suppressed by erasing one of the empty lines. For instance:

This a first paragraph.

\texttt{\label\{label\}}

This is another paragraph.

A similar situation occurs when a sectioning command is followed by \texttt{\label} and a paragraph break:

\texttt{\section\{A section\} \label\{section:label\}}

First paragraph.
Produced HTML is, after a few cosmetic simplifications:

```html
<h2>First paragraph.</h2>

In all cases, this amounts to avoiding a paragraph whose contents consists in a sole \label command.

3.1.2 Spaces after Commands

Space after commands with no argument is skipped. Consider the following example:

```
\newcommand{\open}{}
\newcommand{\close}{}
\open text opened by "\verb+\open+"
and closed by "\verb+\close+"\close.
```

We get:

```
{text opened by "\open" and closed by "\close"}.
```

In the output above, the space after \open does not find its way to the output. More generally, \HVEA tries to emulate \LaTeX behavior in all situations, but discrepancies probably exist. Thus, users are invited to make explicit what they want. This is good practice anyway, because \LaTeX is mysterious here. Consider the following example, where the \texttt{\text{tryspace}} macro is first applied and then expanded by hand:

```
\newcommand{\bfseries}{\textbf{symbol}}
\newcommand{\tryspace}{\ttfamily{[1]{#1 XXX}}}

Some space: \texttt{\text{tryspace}{\bfseries symbol}\\}

No space: \texttt{bfseries symbol XXX}
```

Spacing is a bit chaotic here, the space after symbol remains when \texttt{#1} is substituted for it by \LaTeX (or \texttt{\text{HVEA}}).

```
Some space: symbol XXX
No space : symbolXXX
```

Note that, if a space before “XXX” is wanted, then one should probably write:

```
\newcommand{\tryspace}{[1]{#1} XXX}
```

Finally, whether the tabulation character is a space or not is random, so avoid tabs in your source document.
3.2 Math mode

\[ \text{\LaTeX} \] math mode is not very far from normal text mode, except that all letters are shown in italics and that space after macros is echoed.

However, typesetting math formulas in HTML rises two difficulties. First, formulas contain symbols, such as Greek letters; second, even simple formulas do not follow the simple basic typesetting model of \LaTeX.

3.2.1 Spacing in math mode

By contrast with \LaTeX, spaces from the input are significant in math mode, this feature allows users to instruct \LaTeX on how to put space in their formulas. For instance, $\alpha \rightarrow \beta$ is typeset without spaces between symbols, whereas $\alpha \ \rightarrow \ \beta$ produces these spaces. Note that \LaTeX ignores spaces in math mode, so that users can freely adjust \LaTeX output without changing anything to \LaTeX output.

3.2.2 Symbols

Figure 1: Some symbols

\begin{align*}
\text{\LaTeX} & : & \in: & \in & \notin: & \notin & \int: & \int & \prod: & \prod \\
\text{\LaTeX} & : & \preceq: & \preceq & \succeq: & \succeq & \cup: & \cup & \cap: & \cap \\
\text{\LaTeX} & : & \subseteq: & \subseteq & \supseteq: & \supseteq
\end{align*}

With respect to previous versions of \LaTeX since the beginning, the treatment of symbols has significantly evolved. Outputting symbols is now performed by using Unicode character references, an option that much more complies with standards than the previous option of selecting a "symbol" font. Observe that this choice is now possible, because more and more browsers correctly display such references. See Figure 1 for a few such symbols.

However, this means that ancient or purposely limited browsers (such as text-oriented browsers) cannot display maths, as translated by \LaTeX. For authors that insist on avoiding symbols that cannot be shown by any browser, \LaTeX offers a degraded mode that outputs text in place of symbols. \LaTeX operates in this mode when given the \texttt{-text-symbols} command-line option. Replacement text is in English. For instance, the "\texttt{\in}\" symbol is replaced by "in". This is far from being satisfactory, but degraded mode may be appropriate for documents than contain few symbols.

3.2.3 Displays

Apart from containing symbols, formulas specify strong typesetting constraints: sub-elements must be combined together following patterns that depart from normal text typesetting. For instance, fractional numerators and denominators must be placed one above the other. \LaTeX handles such constraints in display mode only.

The main two operating modes of \LaTeX are \texttt{text} mode and \texttt{display} mode. Text mode is the mode for typesetting normal text, when in this mode, text items are echoed one following the other and paragraph breaks are just blank lines, both in input and output. The so-called \texttt{displayed}-paragraph environments of \LaTeX (such as \texttt{center} or \texttt{quote}) are rendered by HTML block-level elements (such as \texttt{DIV} or \texttt{BLOCKQUOTE}). Rendering is correct because both \LaTeX displayed environments and HTML block-level elements start a
new line. Conversely, since opening a HTML block-level elements means starting a new line, any text that could appear inside a paragraph must be translated using only HTML text-level elements. H Mona chooses to translate in-text formulas that way.

H Mona display mode allows more control on text placement, since entering display mode means opening a HTML TABLE element and that tables allow to control the relative position of their sub-elements. Displays come in two flavor, horizontal displays and vertical displays. An horizontal display is a one-row table, while a vertical display is a one-column table. These tables holds display sub-elements, displays sub-elements being centered vertically in horizontal display mode and horizontally in vertical display mode.

Display mode is first opened by opening a displaymath environment (e.g. by $\$ or \$\$). Then, sub-displays are opened by LaTeX constructs which require them. For instance, a displayed fraction \textbackslash frac opens a vertical display.

The distinction between text and display modes clearly appears while typesetting math formulas. An in-text formula such as $\\int_1^2 x dx = \textbackslash frac{3}{2}$ appears as $\int_1^2 x dx = \frac{3}{2}$, while the same formula has a better aspect in display mode:

$$\int_1^2 x dx = \frac{3}{2}$$

As a consequence, H Mona is more powerful in display mode and formulas should be displayed as soon as they get a bit complicated. This rule is also true in LaTeX but it is more strict in H Mona, since HTML capabilities to typeset formulas inside text are quite poor. In particular, it is not possible to get in-text “real” fractions or in-text limit-like subscripts.

Users should remember that H Mona is not LaTeX or Beamer and that H Mona author neither is D. E. Knuth nor L. Lamport. Thus, some formulas may be rendered poorly. For instance, two fractions with different denominator and numerator height look strange.

$$\frac{1}{N} \sum_{i=0}^{N} U_i$$

The reason is that vertical displays in an horizontal display are HTML tables that always get centered in the vertical direction. Such a crude model cannot faithfully emulate any LaTeX box placement.

Users can get an idea on how H Mona combines elements in display mode by giving the \textbackslash -dv command-line option, which instructs H Mona to add borders to the TABLE elements introduced by displays.

3.2.4 Arrays and display mode

By contrast with formulas, which H Mona attempts to render with text-level elements only when they appear inside paragraphs, LaTeX arrays always translate to the block-level element TABLE, thereby introducing non-desired line breaks before and after in-text arrays. As a consequence, in-text arrays yield an acceptable output, only while alone in a paragraph.

However, since in some sense, all HTML tables are displayed, the array and tabular environments implicitly open display mode, thus allowing a satisfactory typesetting of formulas in arrays. More precisely, array elements whose column format specification is 1, c or r are typeset in display mode (see section B.10.2).
3.3 Warnings

When \TeX\ thinks it cannot translate a symbol or construct properly, it issues a warning. This draws user
attention onto a potential problem. However, rendering may be correct.

Note that all warnings can be suppressed with the `-s` (silent) option. When a warning reveals a real
problem, it can often be cured by writing a specific macro. The next two sections introduce \HVA\ macros,
then section 4 describes how to proceed with greater detail.

3.4 Commands

Just like \TeX, \HVA\ can be seen as a macro language, macros are rewritten until no more expansion is
possible. Then, either some characters (such as letters, integers...) are outputted or some internal operation
(such as changing font attributes, or arranging text items in a certain manner) are performed.

This scheme favors easy extension of program capabilities by users. However, predicting program behavior
and correcting errors may prove difficult, since final output or errors may occur after several levels of macro
expansion. As a consequence, users can tailor \HVA\ to their needs, but it remains a subtle task. Nevertheless,
happy \TeX\ users should enjoy customizing \HVA, since this is done by writing \TeX\ code.

3.5 Style choices

\TeX\ and HTML differ in many aspects. For instance, \TeX\ allows fine control over text placement, whereas
HTML does not. More symbols and font attributes are available in \TeX\ than in HTML. Conversely, HTML
has font attributes, such as color, which standard \TeX\ has not.

Therefore, there are many situations where \HVA\ just cannot render the visual effect of \TeX\ constructs.
Here some choices have to be made. For instance, calligraphic letters (`\mathcal`) are rendered in red
`\textcolor{red}{}\textgreater`.

If you are not satisfied with \HVA\ rendering of text style declarations, then you can choose your own, by
redefining the `\text` macros, using `\renewcommand`, the macro redefinition operator of \TeX. The key point
is that you need not worry about \HVA\ internals: just redefine the old-\TeX\ style text-style declarations
(i.e. `\it`, `\sc`, etc...) and everything should get fine:

\renewcommand{\sc}{\bfseries}
\renewcommand{\cal}{\bfseries}
\renewcommand{\it}{\itshape}

(See sections 4 and 5 on how to make such changes while leaving your file processable by \TeX, and
section 10.2 for a more thorough description of customizing type styles).

Note that many of \TeX\ commands and environments are defined in the `hevea.hva` file that \HVA\ loads
before processing any input. These constructs are written using \TeX\ source code, in the end they invoke
\HVA\ internal commands.

Other \TeX\ constructs, such as \TeX\ key constructs or \HVA\ internal commands (see section 8.3), that
require special processing are defined in \HVA\ source code. However, the vast majority of these definitions
can be overridden by a redefinition. This may prove useless, since there is little point in redefining core
constructs such as `\newcommand` for instance.

4 How to detect and correct errors

Most of the problems that occur during the translation of a given \TeX\ file (say `trouble.tex`) can be
detected and solved at the macro-level. That is, most problems induce a macro-related warning and can be
solved by writing a few macros. The best place for these macros is an user style file (say `trouble.hva`) given
as argument to \HVA:

`# hevea trouble.hva trouble.tex`
By doing so, the macros written specially for H\TeX{} are not seen by L\TeX{}. Even better, trouble.tex is not changed at all.

Of course, this will be easier if the L\TeX{} source is written in a generic style, using macros. Note that this style is recommended anyway, since it facilitates the changing and tuning of documents.

### 4.1 H\TeX{} does not know a macro

Consider the following L\TeX{} source excerpt:

You can \texttt{\raisebox{.6ex}{\em raise} text}.

L\TeX{} typesets this as follows:

\begin{quote}
You can \texttt{\raise} text.
\end{quote}

Since \TeX{} does not know about \texttt{\raisebox}, it incorrectly processes this input. More precisely, it first prints a warning message:

\texttt{trouble.tex:34: Unknown macro: \raisebox}

Then, it goes on by translating the arguments of \texttt{\raisebox} as if they were normal text. As a consequence some .6ex is finally found in the HTML output:

\begin{quote}
You can \texttt{.6ex\em raise} text.
\end{quote}

To correct this, you should provide a macro that has more or less the effect of \texttt{\raisebox}. It is impossible to write a generic \texttt{\raisebox} macro for H\TeX{}, because of HTML limitations. However, in this case, the effect of \texttt{\raisebox} is to raise the box \textit{a little}. Thus, the first, numerical, argument to \texttt{\raisebox} can be ignored in a private \texttt{\raisebox} macro defined in trouble.hva:

\begin{verbatim}
\newcommand{\raisebox}[2]{\raisebox{#2}{#1}}
\end{verbatim}

Now, translating the document yields:

\begin{quote}
You can \texttt{\raise} text a little.
\end{quote}

Of course, this will work only when all \texttt{\raisebox} commands in the document raise text a little. Consider, the following example, where text is both raised a lowered a little:

You can \texttt{\raisebox{.6ex}{\em raise}}

or \texttt{\raisebox{-\.6ex}{\em lower} text}.

Which L\TeX{} renders as follows:

\begin{quote}
You can \texttt{\raise} or \texttt{\lower} text.
\end{quote}

Whereas, with the above definition of \texttt{\raisebox}, H\TeX{} produces:

\begin{quote}
You can \texttt{\raise} or \texttt{\lower} text.
\end{quote}

A solution is to add a new macro definition in the trouble.hva file:

\begin{verbatim}
\newcommand{\lowerbox}[2]{\lowerbox{#2}{#1}}
\end{verbatim}
Then, `trouble.tex` itself has to be modified a little.
You can `\raisebox{.6ex}{\em raise}`
or `\lowerbox{-.6ex}{\em lower}` text.
\hvea now produces a satisfying output:

\begin{align*}
\text{You can } & \raisebox{.6ex}{\em raise} \text{ or } \lowerbox{-.6ex}{\em lower} \text{ text.}
\end{align*}

Note that, for the document to remain \LaTeX-processable, it should also contain the following definition for `\lowerbox`:
\begin{verbatim}
\newcommand{\lowerbox}[2]{\raisebox{#1}{#2}}
\end{verbatim}
This definition can safely be placed anywhere in `trouble.tex`, since by \hvea semantics for `\newcommand` (see section B.8.1) the new definition will not overwrite the old one.

### 4.2 \hvea incorrectly interprets a macro

Sometimes \hvea knows about a macro, but the produced HTML does not look good when seen through a browser. This kind of errors is detected while visually checking the output. However, \hvea does its best to issue warnings when such situations are likely to occur.

Consider, for instance, this definition of `\blob` as a small black square.
\begin{verbatim}
\newcommand{\blob}{\rule{.2ex}{1ex}}
\blob \ Blob \blob
\end{verbatim}
Which \LaTeX typesets as follows:

\begin{verbatim}
\blob
\end{verbatim}

\hvea always translates `\rule` as `<hr>`, ignoring size arguments. Hence, it produces the following, wrong, output:

\begin{verbatim}
Blob
\end{verbatim}

We may not be particularly committed to a square blob. In that case, other small symbols would perfectly do the job of `\blob`, such as a bullet (`\bullet`). Thus, you may choose to give `\blob` a definition in `trouble.hvea`:
\begin{verbatim}
\newcommand{\blob}{\bullet}
\end{verbatim}
This new definition yields the following, more satisfying output:

\begin{verbatim}
• Blob •
\end{verbatim}

In case we do want a square blob, there are two alternatives. We can have \LaTeX typeset some subparts of the document and then to include them as images, section 6 explains how to proceed. We can also find a square blob somewhere in the variety of Unicode (or do I mean ISO 10646?) characters, and define `\blob` as a numerical character reference. Here, the character \char{02588} seems ok.
However, beware that not all browsers display all of Unicode...

4.3 **HtMVA crashes**

HtMVA failure may have many causes, including a bug. However, it may also stem from a wrong \LaTeX{} input. Thus, this section is to be read before reporting a bug...

4.3.1 **Simple cases: \LaTeX{} also crashes**

In the following source, environments are not properly balanced:

\begin{flushright}
\begin{quote}
This is right-flushed quoted text.
\end{quote}
\end{flushright}

Such a source will make both \LaTeX{} and HtMVA choke. HtMVA issues the following error message that shows the \LaTeX{} environment that is not closed properly:

./trouble.tex:6: Environment nesting error: html: 'DIV' closes 'BLOCKQUOTE'
./trouble.tex:4: Latex environment 'quote' is pending

Adios

Thus, when HtMVA crashes, it is a good idea to check that the input is correct by running \LaTeX{} on it.

4.3.2 **Complicated cases**

Unfortunately, HtMVA may crash on input that does not affect \LaTeX{}. Such errors usually relate to environment or group nesting.

Consider for instance the following “optimized” version of a quoteright environment:

\begin{environment}{quoteright}{quote}{flushright}{\endquote}

\begin{flushright}
\begin{quote}
This a right-flushed quotation
\end{quote}
\end{flushright}

The \quote{} and \flushright{} constructs are intended to replace \begin{quote} and \begin{flushright}, while \endquote stands for \end{quote}. Note that the closing \endflushright{} is omitted, since it does nothing. \LaTeX{} accepts such an input and produces a right-flushed quotation.

However, HtMVA usually translates \LaTeX{} environments to HTML block-level elements and it requires those elements to be nested properly. Here, \quote{} translates to <BLOCKQUOTE>, \flushright{} translates to <DIV ALIGN=right> and \endquote translates to </BLOCKQUOTE>. At that point, HtMVA refuses to generate obviously non-correct HTML and it crashes:
Giving up command: \@close
Giving up command: \endquote
Giving up command: \endquoteright
Giving up command: \end
./trouble.tex:7: Environment nesting error: html: 'BLOCKQUOTE' closes 'DIV'
./trouble.tex:5: Latex environment 'quoteright' is pending
Adios

Also notice that the error message above includes a backtrace showing the call-chain of commands.
In this case, the solution is easy: environments must be opened and closed consistently. \LaTeX\ style being recommended, one should write:
\begin{quote}
{\begin{flushright}
\end{quote}

And we get:

This is a right--flushed quotation

Unclosed \LaTeX\ groups (\ldots) are another source of nuisance to \HVM.\ Consider the following \texttt{horreur.tex} file:

\begin{verbatim}
\documentclass{article}

\begin{document}
In this sentence, a group is opened now {\em and never closed.\}
\end{document}
\end{verbatim}

\LaTeX\ accepts this file, although it produces a warning:

# latex horreur.tex
This is TeX, Version 3.14159 (Web2C 7.2)
...
(\end occurred inside a group at level 1)
Output written on horreur.dvi (1 page, 280 bytes).

By contrast, running \HVM\ on \texttt{horreur.tex} yields a fatal error:

# hevea horreur.tex
Giving up command: \raise@enddocument
Giving up command: \enddocument
Giving up command: \end
./horreur.tex:4: Environment nesting error: Latex env error: 'document' closes '
./horreur.tex:3: Latex environment '' is pending
Adios

Thus, users should close opening braces where it belongs. Note that \HVM\ error message “Latex environment ‘env’ is pending” helps a lot in locating the brace that hurts.

4.3.3 Desperate cases
If \HVM\ crashes on \LaTeX\ source (not on \TeX\ source), then you may have discovered a bug, or this manual is not as complete as it should. In any case, please report to Luc.Marangle@inria.fr.

To be useful, your bug report should include \LaTeX\ code that triggers the bug (the shorter, the better) and mention \HVM\ version number.
5 Making \texttt{H\texttt{\texttt{E}}\texttt{V\texttt{A}}} and \texttt{L\texttt{A}T\texttt{E}X} both happy

A satisfactory translation from \texttt{L\texttt{A}T\texttt{E}X} to HTML often requires giving instructions to \texttt{H\texttt{V\texttt{A}}}. Typically, these instructions are macro definitions and these instructions should not be seen by \texttt{L\texttt{A}T\texttt{E}X}. Conversely, some source that \texttt{L\texttt{A}T\texttt{E}X} needs should not be processed by \texttt{H\texttt{V\texttt{A}}}. Basically, there are three ways to make input vary according to the processor, file loading, the \texttt{hevea} package and comments.

5.1 File loading

\texttt{H\texttt{V\texttt{A}}} and \texttt{L\texttt{A}T\texttt{E}X} treat files differently. Here is a summary of the main differences:

- \texttt{L\texttt{A}T\texttt{E}X} and \texttt{H\texttt{V\texttt{A}}} both load files given as arguments to \texttt{\textbackslash input}, however when given the option \texttt{-e filename}, \texttt{H\texttt{V\texttt{A}}} does not load \texttt{filename}.
- \texttt{H\texttt{V\texttt{A}}} loads all files given as command-line arguments.
- Both \texttt{L\texttt{A}T\texttt{E}X} and \texttt{H\texttt{V\texttt{A}}} load style files given as optional arguments to \texttt{\textbackslash documentstyle} and as arguments to \texttt{\textbackslash usepackage}, but the files are searched by following different methods and considering different file extensions.

As a consequence, for having a file \texttt{latexonly} loaded by \texttt{L\texttt{A}T\texttt{E}X} only, it suffices to use \texttt{\textbackslash input(late{}only)} in the source and to invoke \texttt{H\texttt{V\texttt{A}}} as follows:

\# \texttt{hevea -e latexonly}...

Having \texttt{heveanonly} loaded by \texttt{H\texttt{V\texttt{A}}} only is more simple: it suffices to invoke \texttt{H\texttt{V\texttt{A}}} as follows:

\# \texttt{hevea heveanonly}...

Finally, if one has an \texttt{H\texttt{V\texttt{A}}} equivalent \texttt{style.hva} for a \texttt{L\texttt{A}T\texttt{E}X} style file \texttt{style.sty}, then one should load the file as follows:

\texttt{\textbackslash usepackage{style}}

This will result in, \texttt{L\texttt{A}T\texttt{E}X} loading \texttt{style.sty}, while \texttt{H\texttt{V\texttt{A}}} loads \texttt{style.hva}. As \texttt{H\texttt{V\texttt{A}}} will not fail in case \texttt{style.hva} does not exist, this is another method for having a style file loaded by \texttt{L\texttt{A}T\texttt{E}X} only.

Writing an \texttt{H\texttt{V\texttt{A}}} specific file \texttt{file.hva} is the method of choice for supplying command definitions to \texttt{H\texttt{V\texttt{A}}} only. Users can then be sure that these definitions are not seen by \texttt{L\texttt{A}T\texttt{E}X} and will not get echoed to the \texttt{image} file (see section 6).

The file \texttt{file.hva} can be loaded by either supplying the command-line argument \texttt{file.hva}, or by \texttt{\textbackslash usepackage{file}} from inside the document. Which method is better depends on whether you choose to override or to replace the document definition. In the command-line case, definitions from \texttt{file.hva} are processed before the ones from the document and will override them, provided the document definitions are made using \texttt{\textbackslash newcommand} (or \texttt{\textbackslash newenvironment}). In the \texttt{\textbackslash usepackage} case, \texttt{H\texttt{V\texttt{A}}} loads \texttt{file.hva} at the place where \texttt{L\texttt{A}T\texttt{E}X} loads \texttt{file.sty}, hence the definitions from \texttt{file.hva} replace the definitions from \texttt{file.sty} in the strict sense.

5.2 The \texttt{hevea} package

The \texttt{hevea.sty} style file is intended to be loaded by \texttt{L\texttt{A}T\texttt{E}X} and not by \texttt{H\texttt{V\texttt{A}}}. It provides \texttt{L\texttt{A}T\texttt{E}X} with means to ignore or process some parts of the document. Note that \texttt{H\texttt{V\texttt{A}}} copes with the constructs defined in the \texttt{hevea.sty} file by default. It is important to notice that the \texttt{hevea.sty} style file from the distribution is a \texttt{package} in \texttt{L\texttt{A}T\texttt{E}X 2\epsilon} terms and that it is not compatible with old \texttt{L\texttt{A}T\texttt{E}X}. Moreover, the \texttt{hevea} package loads the \texttt{comment} package which must be present. Also notice that, for compatibility, \texttt{H\texttt{V\texttt{A}}} reverts to \texttt{\textbackslash usepackage{hevea}} by loading its own version of the \texttt{comment} package (Section B.17.6).
5.2.1 Environments for selecting a translator

\verb+HBWA+ and \verb+\LaTeX+ perform the following actions on source inside the \texttt{latexonly}, \texttt{verblatex}, \texttt{htmlonly}, \texttt{rawhtml}, \texttt{toimage} and \texttt{verbatim} environments:

<table>
<thead>
<tr>
<th>environment</th>
<th>HBWA</th>
<th>\LaTeX</th>
</tr>
</thead>
<tbody>
<tr>
<td>latexonly</td>
<td>ignore, \texttt{\end{env}} constructs are processed (see section 5.2.2)</td>
<td>process</td>
</tr>
<tr>
<td>verblatex</td>
<td>ignore</td>
<td>process</td>
</tr>
<tr>
<td>htmlonly</td>
<td>process</td>
<td>ignore</td>
</tr>
<tr>
<td>rawhtml</td>
<td>echo verbatim (see section 8.4)</td>
<td>ignore</td>
</tr>
<tr>
<td>toimage</td>
<td>send to the \texttt{image} file, \texttt{\end{env}} constructs and macro characters are processed (see section 6)</td>
<td>process</td>
</tr>
<tr>
<td>verbatim</td>
<td>send to the \texttt{image} file (see section 6)</td>
<td>process</td>
</tr>
</tbody>
</table>

As an example, this is how some text can be typeset in purple by \verb+HBWA+ and left alone by \LaTeX:

We get:
\begin{verbatim}
\textcolor{purple}{\texttt{\begin{htmlonly}\%
\purple \texttt{purple rain, purple rain}%
\end{htmlonly}}
\begin{latexonly}\%
purple \texttt{purple rain, purple rain}%
\end{latexonly}\%
\dots
\end{verbatim}

We get: purple rain, purple rain...

It is impossible to avoid the spurious space in \verb+HBWA+ output for the source above. This extra space comes from the newline character that follows \texttt{\end{htmlonly}}. Namely this construct must appear in a line of its own for \LaTeX to recognize it. Anyway, better control over spaces can be achieved by using the \verb+\hevea+ boolean register or comments, see sections 5.2.3 and 5.3.

Also note that environments define a scope and that style changes (and non-global definitions) are local to them. For instance, in the example above, "..." appears in black in HTML output. However, as an exception, the environments \texttt{image} and \texttt{verbatim} do not create scope. It takes a little practice of \verb+HBWA+ to understand why this is convenient.

5.2.2 Why are there two environments for ignoring input?

Some scanning and analysis of source is performed by \verb+HBWA+ inside the \texttt{latexonly} environment, in order to allow \texttt{latexonly} to dynamically occur inside other environments.

More specifically, \texttt{\end{env}} macros are recognized and their \texttt{env} argument is tested against the name of the environment whose opening macro \texttt{env} opened the \texttt{latexonly} environment. In that case, macro expansion of \texttt{\end{}env} is performed and any further occurrence of \texttt{\end{env}} is tested and may get expanded if it matches a pending \texttt{\begin{env}} construct.

This enables playing tricks such as:

\begin{verbatim}
\newenvironment{latexhuge}
{\begin{latexonly}\huge}
{\end{latexonly}}

\begin{latexhuge}
This will appear in huge font in \verb+\LaTeX+ output only.
\end{latexhuge}
\end{verbatim}

\LaTeX output will be:
This will appear in huge font in \LaTeX output only.

While there is no \verb!verbatim! output.

Since \verb!verbatim! somehow analyses input that is enclosed in the \verb!latexonly! environment, it may choke. However, this environment is intended to select processing by \LaTeX{} only and might contain arbitrary source code. Fortunately, it remains possible to have input processed by \LaTeX{} only, regardless of what it is, by enclosing it in the \verb!verbatim! environment. Inside this environment, \verb!verbatim! performs no other action than looking for \verb!\end{verbatim}. As a consequence, the \verb!\begin{verbatim} and \verb!\end{verbatim} constructs may only appear in the main flow of text or inside the same macro body, a bit like \LaTeX{} verbatim environment.

Relations between \verb!toimage! and \verb!verbatim! are similar. Additionally, formal parameters \verb!#i! are replaced by actual arguments inside the \verb!toimage! environment (see end of section 6.3 for an example of this feature).

5.2.3 The hevea boolean register

Boolean registers are provided by the \verb!ifthen! package (see \LaTeX{}, Section C.8.5 and section B.8.5 in this document). Both the \verb!hevea! style file and \verb!verbatim! define the boolean register \verb!hevea!. However, this register initial value is \verb!false! for \LaTeX{} and \verb!true! for \verb!verbatim!.

Thus, provided, both the \verb!hevea! style file and the \verb!ifthen! packages are loaded, the “purple rain” example can be rephrased as follows:

We get:
\begin{verbatim}
{\ifthenelse{\boolean{hevea}}{\textcolor{purple}{purple rain, purple rain}}{}}\ldots
\end{verbatim}

We get: purple rain, purple rain...

Another choice is using the \TeX{}-style conditional macro \verb!\ifhevea! (see Section B.16.1.4):

We get:
\begin{verbatim}
{\ifhevea\textcolor{purple}{purple}\if purple rain, purple rain\fi}{}}\ldots
\end{verbatim}

We get: purple rain, purple rain...

5.3 Comments

\verb!verbatim! processes all lines that start with \verb!\%HEVEA!, while \LaTeX{} treats these lines as comments. Thus, this is a last variation on the “purple rain” example:

We get:
\begin{verbatim}
\%HEVEA\textcolor{purple}{purple rain, purple rain}\%
\%HEVEA\%
\ldots
\end{verbatim}

(Note how comments are placed at the end of some lines to avoid spurious spaces in the final output.)

We get: purple rain, purple rain...

Comments thus provide an alternative to loading the \verb!hevea! package. For user convenience, comment equivalents to the \verb!latexonly! and \verb!toimage! environment are also provided:
6 With a little help from \texttt{\LaTeX}

Sometimes, \texttt{H\!V\!A} just cannot process its input, but it remains acceptable to have \LaTeX process it, to produce an image from \LaTeX output and to include a link to this image in \texttt{H\!V\!A} output. \texttt{H\!V\!A} provides a limited support for doing this.

6.1 The \texttt{image} file

While outputting \texttt{doc.html}, \texttt{H\!V\!A} echoes some of its input to the \texttt{image} file, \texttt{doc.image.tex}. Part of this process is done at the user’s request. More precisely, the following two constructs send \texttt{text} to the \texttt{image} file:

\begin{verbatim}
\begin{toimage}
\text
\end{toimage}
\end{verbatim}

\texttt{\begin{image} text \end{image}}

Additionally, \texttt{\usepackage} commands, top-level and global definitions are automatically echoed to the image file. This enables using document-specific commands in \texttt{text} above.

Output to the image file builds up a current page, which is flushed by the \texttt{\imagereset} command. This command has the following effect: it outputs a strict page break in the \texttt{image} file, increments the image counter and output a \texttt{<IMG \texttt{Src=”\texttt{pagename.png}“}>} tag in \texttt{H\!V\!A} output file, where \texttt{pagename} is built from the image counter and \texttt{H\!V\!A} output file name. Then the \texttt{image} script has to be run by:

\begin{verbatim}
# imagen doc
\end{verbatim}

This will process the \texttt{doc.image.tex} file through \LaTeX, \texttt{dvips}, \texttt{ghostscript} and a few others tools, which must all be present (see section C.4.1), finally producing one \texttt{pagename.png} file per page in the \texttt{image} file.

The usage of \texttt{imagen} is described at section C.1.5. Note that \texttt{imagen} is a simple shell script. Unix users can pass \texttt{hevea} the command-line option \texttt{-fix}. Then \texttt{hevea} will itself call \texttt{imagen}, when appropriate.

6.2 A toy example

Consider the “blob” example from section 4.2. Here is the active part of a \texttt{blob.tex} file:

\begin{verbatim}
\newcommand{\blob}{\rule{.2ex}{1ex}\{1ex}}
\blob \ Blob \ blob
\end{verbatim}

This time, we would like \texttt{\blob} to produce a small black square, which \texttt{\rule{.2ex}{1ex}\{1ex}} indeed does in \LaTeX. Thus we can write:

\begin{verbatim}
\newcommand{\blob}{\rule{.2ex}{1ex}\{1ex}}
\end{verbatim}
Now we issue the following two commands:

```latex
# hevea blob.tex
# imagen blob
```

And we get:

```
[ Blob ]
```

Observe that the trick can be used to replace missing symbols by small .png images. However, the cost may be prohibitive, text rendering is generally bad, fine placement is ignored and font style changes are problematic. Cost can be lowered using \savebox, but the other problems remain.

### 6.3 Including Postscript images

In this section, a technique to transform included Postscript images into included bitmap images is described. Note that this technique is used by \BVEA implementation of the graphics package (see section B.14.1), which provides a more standard manner to include Postscript images in \LaTeX\ documents.

Included images are easy to manage: it suffices to let \LaTeX\ do the job. Let `round.ps` be a Postscript file, which is included as an image in the source file `round.tex` (which must load the \epsf\ package):

```latex
\begin{center}
\epsfbox{round.ps}
\end{center}
```

Then, \BVEA can have this image translated into a inlined (and centered) .png image by modifying source as follows:

```latex
\begin{center}
\%BEGIN IMAGE
\epsfbox{round.ps}
\%END IMAGE
\%HEVEA\imageflush
\end{center}
```

(Note that the `round.tex` file still can be processed by \LaTeX, since comment equivalents of the \toimage environment are used and that the \imageflush command is inside a \HEVEA comment — see section 5.3.)

Then, processing `round.tex` through \BVEA and `imagen` yields:
It is important to notice that things go smoothly because the \usepackage{epstopdf} command gets echoed to the image file. In more complicated cases, \LaTeX{} may fail on the image file because it does not load the right packages or define the right macros.

However, the above solution implies modifying the original \LaTeX{} source code. A better solution is to define the \epstopdfbox command, so that \LaTeX{} echoes \epstopdfbox and its argument to the image file and performs \imagetocalc:

\begin{verbatim}
\newcommand{\epstopdfbox}{\%}
\begin{imagebox}
\epstopdfbox{#1}
\end{imagebox}
\end{verbatim}

Such a definition must be seen by \LaTeX{} only. So, it is best put in a separate file whose name is given as an extra argument on \LaTeX{} command-line (see section 5.1). Putting it in the document source protected inside an %HEVEA comment is a bad idea, because it might then get echoed to the image file and generate trouble when \LaTeX{} is later run by imagemagick.

Observe that the above definition of \epstopdfbox is a definition and not a redefinition (i.e. \newcommand is used and not \renewcommand), because \LaTeX{} does not know about \epstopdfbox by default. Also observe that this is not a recursive definition, since commands do not get expanded inside the toimage environment.

Finally, if the Postscript image is produced from a bitmap, it is a pity to translate it back into a bitmap. A better idea is first to generate a PNG file from the bitmap source independently and then to include a link to that PNG file in HTML output, see section 8.2 for a description of this more adequate technique.

### 6.4 Using Filters

Some programs extend \LaTeX{} capabilities using a filter principle. In such a scheme, the document contains source fragments for the program. A first run of the program on \LaTeX{} source changes these fragments into constructs that \LaTeX{} (or a subsequent stage in the paper document production chain, such as dvips) can handle. Here again, the rule of the game is keeping \LaTeX{} away from the normal process: first applying the filter, then making \LaTeX{} send the filter output to the image file, and then having imagemagick do the job.

Consider the gpic filter, for making drawings. Source for gpic is enclosed in .PS... .PE, then the result is available to subsequent \LaTeX{} source as a \LaTeX{} box \verb|\box|\verb|graph|. For instance the following source, from a \verb|smile.tex| file, draws a “Smile!” logo as a centered paragraph:

\begin{verbatim}
.PS
e\ellipte "{(Large\bf Smile!)"
.PE
\begin{center}
\box graph
\end{center}
\end{verbatim}
Both the image description (.PS .PE) and usage (\box\graph) are for the image file, and they should be enclosed by \BEGIN IMAGE \END IMAGE comments. Additionally, the image link is put where it belongs by an \imageflush command:

\BEGIN IMAGE
  .PS
  ellipse "{\Large\itf bf Smile!}"  
  .PE
\END IMAGE
\BEGIN IMAGE
\begin{center}
  \box\graph
\end{center}
\END IMAGE
\HEVEA\imageflush
\end{center}

The \gpic filter is applied first, then come hevea and \imagen:

# \gpic -t < smile.tex > tmp.tex
# hevea tmp.tex -o smile.html
# \imagen smile

And we get:

Smile!

Observe how the -o argument to H\hva is used and that \imagen argument is H\hva output basename (see section C.1.1.2 for the full definition of H\hva output basename).

In the \gpic example, modifying user source cannot be totally avoided. However, writing in a generic style saves typing. For instance, users may define the following environment for centered \gpic pictures in \hvaX:

\newenvironment{centergpic}{\begin{center}\begin{graph}\end{center}}

Source code will now be as follows:

\begin{centergpic}
  .PS
  ellipse "{\Large\itf bf Smile!}"  
  .PE
\end{centergpic}

H\hva will process this source correctly, provided it is given its own definition for the \centergpic environment beforehand:

\newenvironment{centergpic}{\begin{toimage}}
  {\begin{graph}\end{toimage}\begin{center}\imageflush\end{center}}

Assuming that the definition above is in a smile.hva file, the command sequence for translating smile.tex now is:
The warnings above are normal: they are issued when HAVA runs across the \texttt{EX}Tended definition of the \texttt{centerpgic} environment and refuses to override its own definition for that environment.

7 Cutting your document into pieces with HAVA

HAVA outputs a single \texttt{.html} file. This file can be cut into pieces at various sectional units by HAVA.

7.1 Simple usage

First generate your \texttt{html} document by applying HAVA:

\begin{verbatim}
# hevea doc.tex
\end{verbatim}

Then cut \texttt{doc.html} into pieces by the command:

\begin{verbatim}
# hacha doc.html
\end{verbatim}

This will generate a simple root file \texttt{index.html}. This root file holds document title, abstract and a simple table of contents. Every item in the table of contents contains a link to or into a file that holds a ‘cutting’ sectional unit. By default, the cutting sectional unit is \texttt{section} in the \texttt{article} style and \texttt{chapter} in the \texttt{book} style. The name of those files are \texttt{doc001.html}, \texttt{doc002.html}, etc.

Additionally, one level of sectioning below the cutting unit (\textit{i.e.} subsections in the \texttt{article} style and sections in the \texttt{book} style) is shown as an entry in the table of contents. Sectional units above the cutting section (\textit{i.e.} parts in both \texttt{article} and \texttt{book} styles) close the current table of contents and open a new one. Cross-references are properly handled, that is, the local links generated by HAVA are changed into remote links.

The name of the root file can be changed using the \texttt{-o} option:

\begin{verbatim}
# hacha -o root.html doc.html
\end{verbatim}

Some of HAVA output get replicated in all the files generated by HAVA. Users can supply a header and a footer, which will appear at the beginning and end of every page generated by HAVA. It suffices to include the following commands in the document preamble:

\begin{verbatim}
\htmlhead{header}
\htmlfoot{footer}
\end{verbatim}

HAVA also makes every page it generates a clone of its input as regards attributes to the \texttt{<BODY ...>}
opening tag and meta-information from the \texttt{<HEAD>...<\HEAD>} block. See section B.2 for examples of this replication feature.

By contrast, style information specified in the \texttt{STYLE} elements from rom the \texttt{<HEAD>...<\HEAD>} block is not replicated. Instead, all style definitions are collected into an external style sheet file whose name is \texttt{doc.css}, and all generated \texttt{html} files adopt \texttt{doc.css} as an external style sheet. It is important to note that, since version 1.08, HAVA produces a \texttt{STYLE} element by itself, even if users do not explicitly use styles. As a consequence, HAVA normally produces a file \texttt{doc.css}, which should not be forgotten while copying files to their final destination after a run of HAVA.
7.2 Advanced usage

HAOA behavior can be altered from the document source, by using a counter and a few macros.

A document that explicitly includes cutting macros still can be typeset by \TeX, provided it loads the \texttt{hevea} style file from the \texttt{HB\&A} distribution. (See section 5 for details on this style file). An alternative to loading the \texttt{hevea} package is to put all cutting instructions in comments starting with \texttt{\%^HEVEA}.

7.2.1 Principle

HAOA recognizes all sectional units, ordered as follows, from top to bottom: \emph{part}, \emph{chapter}, \emph{section}, \emph{subsection}, \emph{subsubsection}, \emph{paragraph} and \emph{subparagraph}.

At any point between \texttt{\begin{document}} and \texttt{\end{document}}, there exist a current cutting sectional unit (cutting unit for short), a current cutting depth, a root file and an output file. Table of contents output goes to the root file, normal output goes to the output file. Cutting units start a new output file, whereas units comprised between the cutting unit and the cutting units plus the cutting depth add new entries in the table of contents.

At document start, the root file and the output file are HAOA output file \texttt{(i.e. index.html)}. The cutting unit and the cutting depth are set to default values that depend on the document style.

7.2.2 Cutting macros

The following cutting instructions are for use in the document preamble. They command the cutting scheme of the whole document:

\texttt{\textbackslash cuttingunit} This is a macro that holds the document cutting unit. You can change the default (which is \emph{section} in the \emph{article} style and \emph{chapter} in the \emph{book} style) by doing:

\texttt{\renewcommand\{\textbackslash cuttingunit\}\{\textit{seccname}\}}.

\texttt{tocnumber} Instruct \texttt{HB\&A} to put section numbers into table of content entries.

\texttt{notocnumber} Instruct \texttt{HB\&A} \emph{not} to put section numbers into table of content entries. This is the default.

\texttt{cuttingdepth} This is a counter that holds the document cutting depth. You can change the default value of 1 by doing \texttt{\setcounter\{cuttingdepth\}\{numvalue\}}. A cutting depth of zero means no other entries than the cutting units in the table of contents.

Other cutting instructions are to be used after \texttt{\begin{document}}. They all generate \texttt{HTML} comments in \texttt{HB\&A} output. These comments then act as instructions to HAOA.

\texttt{\cuthere\{seccname\}\{itemtitle\}} Attempt a cut.

- If \texttt{seccname} is the current cutting unit or the keyword \texttt{now}, then a new output file is started and an entry in the current table of contents is generated, with title \texttt{itemtitle}. This entry holds a link to the new output file.
- If \texttt{seccname} is above the cutting unit, then the current table of contents is closed. The output file is set to the current root file.
- If \texttt{seccname} is below the cutting unit and less than the cutting depth away from it, then an entry is added in the table of contents. This entry contains \texttt{itemtitle} and a link to the point where \texttt{\cuthere} appears.
- Otherwise, no action is performed.

\texttt{\cuted[depth]\{seccname\}} Open a new table of contents, with cutting depth \texttt{depth} and cutting unit \texttt{seccname}. If the optional \texttt{depth} is absent, the cutting depth does not change. The output file becomes the root file. Result is unspecified if whatever \texttt{seccname} expands to is a sectional unit name above the current cutting unit, is not a valid sectional unit name or if \texttt{depth} does not expand to a small positive number.

26
\cutoend End the current table of contents. This closes the scope of the previous \cuto def. The cutting unit and cutting depth are restored. Note that \cuto def and \cutoend must be properly balanced.

Commands \cutothere and \cutoend have starred variants, which behave identically except for footnotes (see 7.3.6).

Default settings work as follows: \begin{document} performs
\cuto def = [value{cutting depth}] {cuttingunit}
and \end{document} performs \cutoend. All sectioning commands perform \cutothere, with the sectional unit name as first argument and the (optional, if present) sectioning command argument (i.e. the section title) as second argument. Note that starred versions of the sectioning commands also perform cutting instructions.

7.2.3 Table of links organization

A table of links generated by \LaTeX is a list of links to generated files. Additionally, some sublists may be present, up to a certain depth. The items in those sublists are links inside generated files, they point to sectional unit titles below the cutting unit, up to a certain depth.

More precisely, let \textit{A} be a certain sectional unit (e.g. “part”), let \textit{B} be just below \textit{A} (e.g. “section”), and let \textit{C} be just below \textit{B} (e.g. “subsection”). Further assume that cutting is performed at level \textit{B} with a depth of more than one. Then, every unit \textit{A} holds a one or several tables of links to generated files, and each generated file normally holds a \textit{B} unit. Sublists with links to \textit{C} units inside \textit{B} units normally appear in the tables of links of level \textit{A}. The command-line options -tocbis and -tocter instruct \LaTeX to put sublists at other places. With -tocbis sublists are duplicated at the beginning of the \textit{B} level files; while with -tocter sublist only appear at the beginning of the \textit{B} level files.

In my opinion, default style is appropriate for documents with short \textit{B} units; while -tocbis style is appropriate for documents with long \textit{B} units with a few sub-units; and -tocter style is appropriate for documents with long \textit{B} units with a lot of sub-units.

Whatever the style is, if a \textit{B} unit is cut (e.g. because its text is enclosed in \cuto def\{C\}... \cutoend), then every \textit{C} unit goes into its own file and there is no sublist after the relevant \textit{B} level entry in the \textit{A} level table of links.

7.2.4 Examples

Consider, for instance, a book document with a long chapter that you want to cut at the section level, showing subsections:

\[ \text{\chapter{A long chapter}} \]
\[ \text{......} \]
\[ \text{\chapter{The next chapter}} \]

Then, you should insert a \cuto def at chapter start and a \cutoend at chapter end:

\[ \text{\chapter{A long chapter}} \]
\%HEVEA\cuto def [1]{section}
\[ \text{......} \]
\%HEVEA\cutoend
\[ \text{\chapter{The next chapter}} \]

Then, the file that would otherwise contain the long chapter now contains the chapter title and a table of sections. No other change is needed, since the command \texttt{\section} already performs the appropriate \texttt{\cutothere\{section\}} commands, which were ignored by default. (Also note that cutting macros are placed inside \texttt{\%HEVEA} comments, for \texttt{\LaTeX} not to be disturbed).
The \cuthere macro can be used to put some document parts into their own file. This may prove appropriate for long cover pages or abstracts that would otherwise go into the root file. Consider the following document:
\documentclass{article}
\begin{document}
\begin{abstract} A big abstract \end{abstract}
...
Then, you make the abstract go to its own file as it was a cutting unit by typing:
\documentclass{article}
\usepackage{hevea}
\begin{document}
\cuthere{cutting unit}{Abstract}
\begin{abstract} A big abstract \end{abstract}
...
(Note that, this time, cutting macros appear unprotected in the source. However, \LaTeX\ still can process the document, since the \texttt{hevea} package is loaded).

7.2.5 More and More Pages in Output
In some situations it may be appropriate to produce many pages from one source file. More specifically, loading the deepcut package will put all sectioning units of your document (from \texttt{part} to \texttt{subsection} in their own file.

Similarly, loading the \texttt{figcut} package will make all figures and tables go into their own file. The \texttt{figcut} package accepts two options, \texttt{show} and \texttt{noshow}. The former, which is the default, instructs \LaTeX\ to repeat the caption into the main flow of text, with a link to the figure. The latter option disables the feature.

7.3 More Advanced Usage
In this section we show how to alter some details of \TeX behavior. This includes controlling output file names and the title of generated web pages and introducing arbitrary cuts.

7.3.1 Controlling output file names
When invoked as \texttt{hacha doc.html}, \TeX produces a \texttt{index.html} table of links file that points into \texttt{doc001.html}, \texttt{doc002.html}, etc. content files. This is not very convenient when one wishes to point inside the document from outside. However, the \texttt{\cutname{name}} command sets the name of the current output file name as \texttt{name}.

Consider a document cut at the section level, which contains the following important section:
\begin{section}{Important\label{important} section}
...
To make the important section goes into file \texttt{important.html}, one writes:
\begin{section}{Important\label{important} section}\cutname{important.html}
...
Then, section “Important section” can be referenced from an \TeX unaware \texttt{html} page by:
In this document, there is a very
\texttt{<A HREF="important.html#important">important section</A>}.  

28
7.3.2 Controlling page titles

When \HvA creates a web page from a given sectional unit, the title of this page normally is the name of the sectional unit. For instance, the title of this very page should be “Cutting your document into pieces with \HvA”. It is possible to insert some text at the beginning of all page titles, by using the `\htmlprefix` command. Hence, by writing `\htmlprefix{hevea Manual: }` in the document, the title of this page would become: “\HvA Manual: Cutting your document into pieces with \HvA” and the title of all other pages would show the same prefix.

7.3.3 Links for the root file

The command `\toplink{prev}{up}{next}` instructs \HvA to put links to a “previous”, “up” and “next” page in the root file. The following points are worth noticing:

- The `\toplink` command must appear in the document preamble (i.e. before `\begin{document}`).
- The arguments `prev`, `up` and `next` should expand to urls, notice that these argument are processed (see section 8.1.1).
- When one of the expected argument is left empty, the corresponding link is not generated.

This feature can prove useful to relate documents that are generated independantly by \HvA and \HvA.

7.3.4 Controlling link aspect from the document

By default the links to the previous, up and next pages show a small icon (an appropriate arrow). This can be changed with the command `\setlinktext{prev}{up}{next}`, where `prev`, `up` and `next` are some \TeX source. For instance the default behavior is equivalent to:

```
\setlinktext
\begin{verbatim}
{\latexsrc[ALT="Previous"]{previous_motif.gif}}
{\latexsrc[ALT="Up"]{contents_motif.gif}}
{\latexsrc[ALT="Next"]{next_motif.gif}}
\end{verbatim}
```

Command `\setlinktext` behaves as `\toplink` does. That is, it must occur in document preamble, arguments are processed and empty arguments yield no effect (i.e. defaults apply).

7.3.5 Cutting a document anywhere

Part of a document goes to a separate file when enclosed in a `\cutflow` environment:

```
\begin{cutflow}{title}...\end{cutflow}
```

The content “…” will go into a file of its own, while the argument `title` is used as the title of the introduced \html page.

The \html page introduced here does not belong to the normal flow of text. Consequently, one needs an explicit reference from the normal flow of text into the content of the \cutflow environment. This will occur naturally when the content of the \cutflow environment contains a `\label` construct. This look natural in the following quiz example:

```
\begin{enumerate}
\item What is black?
\item What is white?
\item What is Dylan?
\end{enumerate}
```

29
Answers in section \ref{answers}.
\begin{cutflow}{Answers}
\paragraph{Quiz answers}\label{answers}
\begin{enumerate}
\item Black is black.
\item White is white.
\item Dylan is Dylan.
\end{enumerate}
\end{cutflow}

However, introducing HTML hyperlink targets and references with the \texttt{\anname} and \texttt{\ahrefloc} commands (see section 8.1.1) will be more practical most of the time.

The starred variant environment \texttt{cutflow*} is the same as \texttt{cutflow}, save for the HTML header and footer (see Section 7.1) which are not replicated in the introduced page.

7.3.6 Footnotes

Footnote texts (given as arguments either to \texttt{\footnote} or \texttt{\footnotetext}) do not go directly to output. Instead, footnote texts accumulate internally in a buffer, awaiting to be flushed. The flushing of notes is controlled by the means of a current flushing unit, which is a sectional unit name or document — a fictional unit above all units. At any point, the current flushing unit is the value of the command \texttt{\footnoteflush}. In practice, the flushing of footnote texts is performed by two commands:

- \texttt{\flushdef\{asename\}} simply sets the flushing unit to \texttt{asename}.

- \texttt{\footnoteflush\{asename\}} acts as follows:
  - If argument \texttt{asename} is equal to or above the current flushing unit, then footnote texts are flushed (if any). In the output, the texts themselves are surrounded by special comments that tag them as footnote texts and record \texttt{asename}.
  - Otherwise, no action is performed.

The \texttt{article} style file performs \texttt{\flushdef\{document\}}, while the \texttt{book} style file performs \texttt{\flushdef\{chapter\}}. At the end of processing, \texttt{\end\{document\}} performs \texttt{\footnoteflush\{\footnoteflush\}}, so as to flush any pending notes.

Cutting commands interact with footnote flushing as follows:

- \texttt{\cuthere\{asename\}} executes \texttt{\footnoteflush\{asename\}}. Remember that all sectioning commands perform \texttt{\cuthere} with their sectional unit name as argument.

- \texttt{\cutdef\{asename\}} saves the current flushing unit and buffer on some internal stack, starts a new buffer for footnote texts, and sets the current flushing unit to \texttt{asename} (by performing \texttt{\flushdef\{asename\}}).

- \texttt{\cutend} first flushes any pending texts (by performing \texttt{\footnoteflush} with the current flushing unit as argument), and restores the flushing unit and footnote text buffer saved by the matching \texttt{\cutdef}.

- The starred variants \texttt{\cutdef*} and \texttt{\cutend*} perform no operation that is related to footnotes.

Later, when running across footnote texts in its input file, \texttt{H\TeX} sometimes puts notes in a separate file. More precisely, \texttt{H\TeX} has knowledge of the current cutting level, the current sectional unit where cuts occur — as given by the relevant \texttt{\cutdef}. Moreover, \texttt{H\TeX} knows the current section level — that is, the last sectional command processed. Besides, \texttt{H\TeX} extracts the note level from the comments that surround the notes (as given by the command \texttt{\footnoteflush} that produced the notes). Then, \texttt{H\TeX} creates a separate file for notes when the cutting level and the note level differ, or when the current level is above the cutting level (e.g., the current level is document while the cutting level is chapter). As a result, notes should stay where they are when they occur at the end of \texttt{H\TeX} output file and otherwise go to a separate file.

30
To make a complicated story even more complicated, footnotes in minipage environments or in the arguments to \title or \author have a different, I guess satisfactory, behavior.

Given the above description, footnotes are managed by default as follows:

- In style article, hevea puts all footnotes go at the end of the HTML file. A later run of hacha creates a separate footnote file.
- In style book, footnotes are collected at the end of chapters. A later run of hacha leaves them where they are. Footnotes in the title or author names are managed specially, they will normally appear at the end of the root file.

In case you wish to adopt a book-like behavior for an article (footnotes at the end of sections), it suffices to insert \flushout[section] in the document preamble.

8 Generating HTML constructs

H\TeX output language being HTML, it is normal for users to insert hypertext constructs their documents, or to control colors.

8.1 High-Level Commands

H\TeX provides high-level commands for generating hypertext constructs. Users are advised to use these commands in the first place, because it is easy to write incorrect HTML and that writing HTML directly may interfere in nasty ways with H\TeX internals.

8.1.1 Commands for Hyperlinks

A few commands for hyperlink management and included images are provided, all these commands have appropriate equivalents defined by the hevea package (see section 5.2). Hence, a document that relies on these high-level commands still can be typeset by \TeX, provided it loads the hevea package.

<table>
<thead>
<tr>
<th>Macro</th>
<th>H\TeX</th>
<th>\TeX</th>
</tr>
</thead>
<tbody>
<tr>
<td>\href{url}{text}</td>
<td>make text an hyperlink to url</td>
<td>echo text</td>
</tr>
<tr>
<td>\footnote{url}{text}</td>
<td>make text an hyperlink to url</td>
<td>make url a footnote to text, url is shown in typewriter font</td>
</tr>
<tr>
<td>\hrefurl{url}</td>
<td>make url an hyperlink to url</td>
<td>typeset url in typewriter font</td>
</tr>
<tr>
<td>\hrefloc{label}{text}</td>
<td>make text an hyperlink to label inside the document</td>
<td>echo text</td>
</tr>
<tr>
<td>\anode{label}{text}</td>
<td>make text an hyperlink target with label label</td>
<td>echo text</td>
</tr>
<tr>
<td>\mailto{address}</td>
<td>make address a “mailto” link to address</td>
<td>typeset address in typewriter font</td>
</tr>
<tr>
<td>\imgsrc{attr}{url}</td>
<td>insert url as an image, attr are attributes in the HTML sense</td>
<td>do nothing</td>
</tr>
<tr>
<td>\home{text}</td>
<td>produce a home-dir url both for output and links, output aspect is: “-text”</td>
<td></td>
</tr>
</tbody>
</table>

It is important to notice that all arguments are processed. For instance, to insert a link to my home page, \texttt{(http://pauillac.inria.fr/~maranget/index.html)}, you should do something like this:

\href{http://pauillac.inria.fr/~maranget/index.html}{his home page}
Given the frequency of ~, # etc. in urls, this is annoying. Moreover, the immediate solution, using \verb, \url\{verb" ... /maranget/..."\} (his home page) does not work, since \LaTeX\ forbids verbatim formatting inside command arguments.

Fortunately, the url package provides a very convenient url command that acts like \verb and can appear in other command arguments (unfortunately, this is not the full story, see section B.17.11). Hence, provided the url package is loaded, a more convenient reformulation of the example above is:

\url\{http://pauillac.inria.fr/~maranget/index.html\} (his home page)

Or even better:

\urldef\{lucpage}\{http://pauillac.inria.fr/~maranget/index.html\}
\url\{lucpage\} (his home page)

It may seem complicated, but this is a safe way to have a document processed both by \LaTeX{} and \Hevea. Drawing a line between url typesetting and hyperlinks is correct, because users may sometime want urls to be processed and some other times not. Moreover, \Hevea (optionally) depends on only one third party package: url, which is as correct as it can be and well-written.

In case the url command is undefined at the time \begin{document} is processed, the commands \url, \oneurl and \footurl are defined as synonyms for \url, \oneurl and \footurl, thereby ensuring some compatibility with older versions of \Hevea. Note that this usage of \url is deprecated.

### 8.1.2 HTML style colors

Specifying colors both for \LaTeX{} and \Hevea should be done using the color package (see section B.14.2). However, one can also specify text color using special type style declarations. The hevea.sty style file define no equivalent for these declarations, which therefore are for \Hevea consumption only.

Those declarations follow HTML conventions for colors. There are sixteen predefined colors:

- \texttt{black, silver, gray, white, maroon, red, fuchsia, purple,}
- \texttt{green, lime, olive, yellow, navy, blue, teal, aqua}

Additionally, the current text color can be changed by the declaration \htmlcolor\{number\}, where number is a six digit hexadecimal number specifying a color in the RGB space. For instance, the declaration \htmlcolor\{404040\} changes font color to dark gray.

### 8.2 More on included images

The \texttt{\imagerc} command becomes handy when one has images both in Postscript and GIF (or PNG or JPG) format. As explained in section 6.3, Postscript images can be included in \LaTeX{} documents by using the \texttt{\epsfbox} command from the epsf package. For instance, if \texttt{screenshot.ps} is an encapsulated Postscript file, then a \texttt{doc.tex} document can include it by:

\texttt{\epsfbox\{screenshot.ps\}}

We may very well also have a GIF version of the screenshot image (or be able to produce one easily using image converting tools), let us store it in a \texttt{screenshot.ps.gif} file. Then, for \Hevea to include a link to the GIF image in its output, it suffices to define the \texttt{\epsfbox} command in the macro.hva file as follows:

\texttt{\newcommand\{\epsfbox\}{\imagerc\}\{#1.gif\}}

Then \Hevea has to be run as:

```
# hevea macros.hva doc.tex
```
Since it has its own definition of \epsfbox, \HVM would silently include a link the GIF image and not to the Postscript image.

If another naming scheme for image files is preferred, there are alternatives. For instance, assume that Postscript files are of the kind \textit{name.ps}, while GIF files are of the kind \textit{name.gif}. Then, images can be included using \texttt{\includeimage{name}}, where \texttt{\includeimage} is a specific user-defined command:

\begin{verbatim}
\newcommand{\includeimage}[1]{\if\ifhvea\includegraphics[\hsize]{#1}\else\epsfbox{#1}\fi}
\end{verbatim}

Note that this method uses the \hvea boolean register (see section 5.2.3). If one does not wish to load the \hvea.sty file, one can adopt the slightly more verbose definition:

\begin{verbatim}
\newcommand{\includeimage}[1]{% 
%HVEA\includegraphics[\hsize]{#1}% 
\begin{LATEX} \epsfbox{#1} \end{LATEX} 
}
\end{verbatim}

When the Postscript file has been produced by translating a bitmap file, this simple method of making a bitmap image and using the \texttt{\includegraphics} command is the most adequate. It should be preferred over using the more automated \texttt{image} file mechanism (see section 6), which will translate the image back from Postscript to bitmap format and will thus degrade it.

\subsection{Internal macros}

In this section a few of \HVM internal macros are described. Internal macros occur at the final expansion stage of \HVM and invoke Objective LaTeX code.

Normally, user source code should not use them, since their behavior may change from one version of \HVM to another and because using them incorrectly easily crashes \HVM. However:

- Internal macros are almost mandatory for writing supplementary base style files.
- Casual usage is a convenient (but dangerous) way to finely control output (cf. the examples in the next section).
- Knowing a little about internal macros helps in understanding how \HVM works.

The general principle of \HVM is that \LaTeX\ environments \begin{env}... \end{env} get translated into \texttt{HTML} block-level elements \texttt{<block attributes>}... \texttt{/</block>}. More specifically, such block level elements are opened by the internal macro \texttt{\open} and closed by the internal macro \texttt{\close}. As a special case, \LaTeX\ groups \{... \} get translated into \texttt{HTML} \texttt{groups}, which are shadow block-level elements with neither opening nor closing tag.

In the following few paragraphs, we sketch the interaction of \texttt{\open}... \texttt{\close} with paragraphs. Doing so, we intend to warn users about the complexity of the task of producing \texttt{correct HTML}, and to encourage them to use internal macros, which, most of the time, take nasty details into account.

Paragraphs are rendered by \texttt{P} elements, which are opened and closed automatically. More specifically, a first \texttt{P} is opened after \begin{document}, then paragraph breaks close the active \texttt{P} and open a new one. The final \end{document} closes the last \texttt{P}. In any occasion, paragraphs consisting only of space characters are discarded silently.

Following \texttt{HTML} “normative reference [HTML-4.0]”, block-level elements cannot occur inside \texttt{P}; more precisely, block-level opening tags implicitly close any active \texttt{P}. As a consequence, \HVM closes the active \texttt{P} element when it processes \texttt{\open} and opens a new \texttt{P} when it processes the matching \texttt{\close}. Generally, no \texttt{P} element is opened by default inside block-level elements, that is, \HVM does not immediately open \texttt{P} after having processed \texttt{\open}. However, if a paragraph break occurs later, then a new \texttt{P} element is opened, and will be closed automatically when the current block is closed. Thus, the first “paragraph” inside block-level
Vegetable text (M/E) (L, C) Declare the text-level element M/E with attribute 'active'. This primitive behaves as (M/E) (L, C) except that the opening tag has attributes. The primitive may prove useful for introducing SMK elements. Note that both arguments are processed.

Very text (M/E) (B, C) Declare the text-level element M/E with attribute 'active'. This primitive behaves as (M/E) (B, C) except that the opening tag has attributes. The primitive may prove useful for introducing SMK elements. Note that both arguments are processed.

Very text (M/E) (B, C) Declare the text-level element M/E with attribute 'active'. This primitive behaves as (M/E) (B, C) except that the opening tag has attributes. The primitive may prove useful for introducing SMK elements. Note that both arguments are processed.

\input{sec/8.4}

8.4 The rawhtml environment

Any text enclosed between `\begin{rawhtml}` and `\end{rawhtml}` is echoed verbatim into the HTML output file. Similarly, `\rawhtmlinput{file}` echoes the contents of file `file`. In fact, rawhtml is the environment counterpart of the `\verbatim` command, but experience showed it to be much more error prone.

When \TeX{} was less sophisticated then it is now, rawhtml was quite convenient. But, as time went by, numerous pitfalls around rawhtml showed up. Here are a few:

- Verbatim means that no translation of any kind is performed. In particular, be aware that input encoding (see B.17.4) does not apply. Hence one should use ascii only, if needed non-ascii characters can be given as entity or numerical character references — e.g. \&eacute{}; or \#192; for é.

- The rawhtml environment should contain only HTML text that makes sense alone. For instance, writing `\begin{rawhtml}<TABLE><ALIGN=right>\end{rawhtml}... \begin{rawhtml}</TABLE>\end{rawhtml}` is dangerous, because \TeX{} is not informed about opening and closing the block-level element \texttt{TABLE}. In that case, one should use the internal macros `\verbatim` and `\endverbatim`.

- \begin{rawhtml}\textend{rawhtml} fragments that contain block-level elements will almost certainly mix poorly with \texttt{P} elements (introduced by paragraph breaks) and with active style declaration (introduced by, for instance, `\it`). Safe usage will most of the time means using the internal macros `\verbatim` and `\endverbatim`.

- When \TeX{} is given the command-line option `-O`, checking and optimization of text-level elements in the whole document takes place. As a consequence, incorrect HTML introduced by using the rawhtml environment may be detected at a later stage, but this is far from being certain.

As a conclusion, do not use the rawhtml environment! A much safer option is to use the htmlonly environment and to write \TeX{} code. For instance, in place of writing:

\begin{verbatim}
\begin{rawhtml}
A list of links:
\begin{ul}
\item \texttt{A HREF="http://www.apple.com/">Apple</A>}
\item \texttt{A HREF="http://www.sun.com/">Sun</A>}
\end{ul}
\end{rawhtml}
\end{verbatim}

One can write:
If H\texttt{V}A is targeted to text or info files (see Section 11). The text inside \texttt{rhtml} environments is ignored. However there exists a \texttt{rtext} environment (and a \texttt{rtextinput} command) to echo text verbatim in text or info output mode. Additionally, the raw environment and a \texttt{rawinput} command echo their contents verbatim, regardless of \texttt{HVEA} output mode. Of course, when \texttt{HVEA} produces \texttt{HTML}, the latter environment and command suffer from the same drawbacks as \texttt{rhtml}.

8.5 Examples

As a first example of using internal macros, consider the following excerpt from the \texttt{hevea.hva} file that defines the \texttt{center} environment:

\begin{verbatim}
\newenvironment{center}{\begin{DIV}{ALIGN=center}}{\end{DIV}}
\end{verbatim}

Notice that the code above is no longer present and is given here for explanatory purpose only. Now \texttt{HVEA} uses style-sheets and the actual definition of the \texttt{center} environment is as follows:

\begin{verbatim}
\newstyle{\text-align: center; margin-left: auto; margin-right: auto; }% \setenvclass{center}% \newenvironment{center}
  {\begin{DIV}{\getprint{CLASS="\envclass{center}"}}}%  {\end{DIV}}% 
\end{verbatim}

Basically environments \texttt{\begin{center}} \ldots \texttt{\end{center}} will, by default, be translated into blocks \texttt{DIV CLASS="center"}. Additionally, the style class associated to \texttt{center} environments is managed through an indirection, using the commands \texttt{setenvclass} and \texttt{getenvclass}. See section 9.3 for more explanations.

Another example is the definition of the \texttt{purple} color declaration (see section 8.1.2):

\begin{verbatim}
\newcommand{\purple}{\color{purple}}
\end{verbatim}

\texttt{HVEA} does not feature all text-level elements by default. However one can easily use them with the internal macro \texttt{\style}. For instance this is how you can make all emphasized text blink:

\begin{verbatim}
\newcommand{\em}{\textbf{EM} \style{BLINK}}
\end{verbatim}

Then, here is the definition of a simplified \texttt{imgsrc} command (see section 8.1.1), without its optional argument:

\begin{verbatim}
\newcommand{\imgsrc}[1]
  {\print{<IMG SRC="\getprint{#1}"></img>}}
\end{verbatim}

Here, \texttt{\print} and \texttt{\getprint} are used to output \texttt{HTML} text, depending upon whether this text requires processing or not. Note that \texttt{\open{IMG}{SRC="#1"}} is not correct, because the element \texttt{IMG} consists in a single tag, without a closing tag.

Another interesting example is the definition of the command \texttt{\doelement}, which \texttt{HVEA} uses internally to output \texttt{A} elements.

\begin{verbatim}
\newcommand{\doelement}[2]
  {{\makestyle{\\print{<A }}\getprint{#1}\\print{>}}#2{\makestyle{\\print{</A>}}}}
\end{verbatim}
The command \closeelement takes two arguments: the first argument contains the opening tag attributes; while the second element is the textual content of the A element. By contrast with the \imgsrc example above, tags are emitted inside groups where styles are canceled by using the \nostyle declaration. Such a complication is needed, so as to avoid breaking proper nesting of text-level elements.

Here is another example of direct block opening. The bgcolor environment from the color package locally changes background color (see section B.14.2.1). This environment is defined as follows:

\newenvironment{bgcolor}[2][CELLPADDING=1] {
  \begin{TABLE}[#1]\begin{TR}\begin{TD}[BGCOLOR=#2]\}
  \end{TD}\end{TR}\end{TABLE}\}

The bgcolor environment operates by opening a HTML table (TABLE) with only one row (TR) and cell (TD) in its opening command, and closing all these elements in its closing command. In my opinion, such a style of opening block-level elements in environment opening commands and closing them in environment closing commands is good style. The one cell background color is forced with a BGColor attribute. Note that the mandatory argument to \begin{bgcolor} is the background color expressed as a high-level color, which therefore needs to be translated into a low-level color by using the \getcolor internal macro from the color package. Additionally, \begin{bgcolor} takes HTML attributes as an optional argument. These attributes are the ones of the TABLE element.

If you wish to output a given unicode character whose value you know, the recommended technique is to define an ad-hoc command that simply call the \printu command. For instance, “blackboard sigma” is Unicode U+02140 (hexa). Hence you can define the command \bbsigma as follows:

\newcommand{\bbsigma}{\printu{X2140}}

8.6 The document charset

According to standards, as I understand them, HTML pages are made of Unicode (ISO 10646) characters. By contrast, a file in any operating system is usually considered as being made of bytes.

To account for that fact, HTML pages usually specify a document charset that defines a translation from a flow of bytes to a flow of characters. For instance, the byte 0xA4 means Unicode 0x00A4 (Ç) in the ISO-8859-1 (or latin1) encoding, and 0x20AC (€) in the ISO-8859-15 (or latin9) encoding. Notice that HTML has no difficulty to output both symbols, in fact they are defined as Unicode characters:

\newcommand{\textcurrency}{\printu{XA4}}
\newcommand{\texteuro}{\printu{X20AC}}

But the \printu command may output the specified character as a byte, when possible, by the means of the output translator. If not possible, \printu outputs a numerical character references (for instance &x20AC;).

Of course, the document charset and the output translator must be synchronized. The command \defchardset takes a charset name as argument and performs the operation of specifying the document character set and the output translator. It should occur in the document preamble. Valid charset names are ISO-8859-n where n is a number in 1...15, KOI8-R, US-ASCII (the default), windows-n where n is 1250, 1251, 1252 or 1257, or macintosh, or UTF-8. In case these charsets do not suffice, you may ask the author for other document charsets. Notice however that document charset is not that important, the default US-ASCII works everywhere! Input encoding of source files is another, although related, issue — see Section B.17.4.

If wished so, the charset can be extracted from the current locale environment, provided this yields a valid (to HTML) charset name. This operation is performed by a companion script: xxcharset.exe. It thus suffices to launch HTML as:

# hevea --exec xxcharset.exe other arguments
9 Support for style sheets

9.1 Overview

Starting with version 1.08, H\TeX \!A offers support for style sheets (of the CSS variant see [CSS-2]).

Style sheets provide enhanced expressiveness. For instance, it is now possible to get “real” (whatever real means here) small caps in HTML, and in a relatively standard manner. There are other, discrete, maybe unnoticed, similar enhancements.

However, style sheets mostly offer an additional mechanism to customize their documents to H\TeX \!A users. To do so, users should probably get familiar with how H\TeX \!A uses style sheets in the first place.

H\TeX \!A interest for style sheets is at the moment confined to block-level elements (DIV, TABLE, H<n>, etc.). The general principle is as follows: when a command or an environment gets translated into a block-level element, the opening tag of the block level element has a \texttt{CLASS="name"} attribute, where \texttt{name} is the command or environment name.

As an example the \texttt{\LaTeX} command \texttt{\subsection} is implemented with the element H3, resulting in HTML output of the form:

\begin{verbatim}
  <H3 CLASS="subsection">
    ...
  </H3>
\end{verbatim}

By default, most styles are undefined, and default rendering of block-level elements applies. However, some packages (such as, for instance fancysection, see Section B.16.4) may define them. If you wish to change the style of section headers, loading the fancysection package may prove appropriate (see B.16.4). However, one can also proceed more directly, by appending new definitions to the document style sheet, with the command \texttt{\newstyle}. For instance, here is a \texttt{\newstyle} to add style for subsections.

\begin{verbatim}
\newstyle{subsection}{padding:1ex; color:navy; border:solid navy;}
\end{verbatim}

This declaration adds some style element to the \texttt{subsection} class (notice the dot!). blocks that declare to belong to the class will show dark-blue text, some padding (space inside the box) is added and a border will be drawn around the block. These specifications will normally affect all subsections in the document.

The following points are worth noticing:

- To yield some effect, \texttt{\newstyle} commands \texttt{must} appear in the document preamble, \textit{i.e.} before \texttt{\begin{document}}.
- Arguments to \texttt{\newstyle} commands are processed.
- The \texttt{hevea} package defines all style sheet related commands as no-ops. Thus, these commands do not affect document processing by \texttt{\LaTeX}.

9.2 Changing the style of all instances of an environment

In this very document, all verbatim environments appear over a light green background, with small left and right margins. This has been performed by simply issuing the following command in the document preamble.

\begin{verbatim}
\newstyle{verbatim}{margin:1ex 1ex;padding:1ex;background:\#cfcfcf;}
\end{verbatim}

Observe that, in the explicit numerical color argument above, the hash character “#” has to be escaped.

9.3 Changing the style of some instances of an environment

One can also change the style class attached to a given instance of an environment and thus control styling of environments more precisely.

As a matter of fact, the name of the class attribute of environment \texttt{env} is referred to through an indirection, by using the command \texttt{\getenvclass{env}}. The class attribute can be changed with the command
\setenvclass{env}{class}. The \setenvclass command internally defines a command \env@class, whose content is read by the \getenvclass command. As a consequence, the class attribute of environments follows normal scoping rules. For instance, here is how to change the style of one verbatim environment.

\setenvclass{verbatim}{myverbatim}
\begin{verbatim}
This will be styled through class 'myverbatim', introduced by:
\newstyle{.myverbatim}
{margin:1ex;padding:1ex;
color:maroon;
background:\getstylecolor[named]{Apricot};}
\end{verbatim}

Observe how the class of environment verbatim is changed from its default value to the new value myverbatim. The change remains active until the end of the current group (here, the "\" at the end). Then, the class of environment verbatim is restored to its default value — which happen to be verbatim.

This example also shows two new ways to specify colors in style definition, with a conventional HTML color name (here maroon) or as a high-level color (see Section B.14.2), given as an argument to the \getstylecolor internal command (here \texttt{Apricot} from the named color model).

A good way of specifying style class changes probably is by defining new environments.

\newenvironment{flashyverbatim}
{\setenvclass{verbatim}{myverbatim}{verbatim}}
{endverbatim}

Then, we can use \begin{flashyverbatim}... \end{flashyverbatim} to get verbatim environments style with the intended myverbatim style class.

### 9.4 Which class affects what

Generally, the styling of environment \texttt{env} is performed through the commands \setenvclass{env} and \setenvclass{env}{...}, with \getenvclass{env} producing the default value of \texttt{env}.

Concretely, this means that most of the environments are styled through an homonymous style class. Here is a non-exhaustive list of such environments

- \texttt{figure}, \texttt{table}, \texttt{itemize}, \texttt{enumerate}, \texttt{list}, \texttt{description}, \texttt{trivlist}, \texttt{center}, \texttt{flushleft}, \texttt{flushright}, \texttt{quote}, \texttt{quotation}, \texttt{verbatim}, \texttt{abstract}, \texttt{mathpar} (cf Section B.15), \texttt{lstlisting} (cf. Section B.17.13), etc.

All sectioning commands (\part, \section etc.) output \texttt{H\textless n\textgreater} block-level elements, which are styled through style classes named \texttt{part}, \texttt{section}, etc.

List making-environment introduce extra style classes for items. More specifically, for list-making environments \texttt{itemize} and \texttt{enumerate}, \texttt{LI} elements are styled as follows:

\begin{verbatim}<UL CLASS="itemize"> ...
<LI CLASS="li-itemize"> ...
</UL>
<OL CLASS="enumerate"> ...
<LI CLASS="li-enumerate"> ...
</OL>
\end{verbatim}

That is, \texttt{LI} elements are styled as environments, the key name being \texttt{li-env}.

The \texttt{description}, \texttt{trivlist} and \texttt{list} environments (which all get translated into \texttt{DL} elements) are styled in a similar way, internal \texttt{DT} and \texttt{DD} elements being styles through names \texttt{dt-env} and \texttt{dd-env} respectively.
9.5 A few examples

9.5.1 The title of the document

The command \maketitle formats the document title within a \texttt{TABLE} element, with class \texttt{title}, for display. The name of the title is displayed inside block H1, with class \texttt{titlemain}, while all other information (author, date) are displayed inside block H3, with class \texttt{titlerest}.

\begin{verbatim}
<TABLE CLASS="title">
  <TR>
    <TD>
      \begin{verbatim}
        <H1 ALIGN=center CLASS="titlemain">..title here..</H1>
        <H3 ALIGN=center CLASS="titlerest">..author here..</H3>
        <H3 ALIGN=center CLASS="titlerest">..date here..</H3>
      \end{verbatim}
    </TD>
  </TR>
</TABLE>
\end{verbatim}

Users can impact on title formatting by adding style in the appropriate style classes. For instance the following style class definitions:

\newstyle{.title}
{\text-align: center; margin:1ex auto; padding:2ex; color:navy; border:solid navy;}
\newstyle{.titlerest}{font-variant:small-caps;}

will normally produce a title in dark blue, centered in a box, with author and date in small-caps.

9.5.2 Enclosing things in a \texttt{divstyle} DIV

At the moment, due to the complexity of the task, \texttt{environments tabular and array} cannot be styled as others environments can be, by defining an appropriate class in the preamble. However, even for such constructs, limited styling can be performed, by using the \texttt{divstyle} environment. The opening command \begin{\texttt{divstyle}}\{class\} takes the name of a class as an argument, and translates to \texttt{\texttt{DIV CLASS="class"}}. Of course the closing command \end{\texttt{divstyle}} translates to \texttt{</DIV}. The limitation is that the enclosed part may generate more \texttt{HTML} blocks, and that not all style attribute defined in class class \texttt{class} will apply to those inner blocks.

As an example consider the style class definition below.

\newstyle{.ruled}{border:solid black; padding:1ex; background:\#e0dbb; color:marron}

The intended behavior is to add a black border around the inner block (with some padding), and to have text over a light brown background.

If we, for instance, enclose an \texttt{itemize} environment, the resulting effect is more or less what we have expected:

\begin{verbatim}
\begin{\texttt{divstyle}}\{ruled\}
\begin{\texttt{itemize}}
\item A ruled itemize
\item With two items.
\end{\texttt{itemize}}
\end{\texttt{divstyle}}
\end{verbatim}

However, enclosing a centered \texttt{tabular} environment in a \texttt{divstyle\{ruled\}} one is less satisfactory.

\begin{verbatim}
\begin{\texttt{divstyle}}\{ruled\}
\begin{\texttt{center}}\begin{\texttt{tabular}}\{|c|c|\}
\end{verbatim}

40

<table>
<thead>
<tr>
<th>English</th>
<th>French</th>
</tr>
</thead>
<tbody>
<tr>
<td>Good Morning</td>
<td>Bonjour</td>
</tr>
<tr>
<td>Thank You</td>
<td>Merci</td>
</tr>
<tr>
<td>Good Bye</td>
<td>Au Revoir</td>
</tr>
</tbody>
</table>

9.5.3 Enclosing things in a styled cell

Given the differences in styling DIV and table elements, HTML provides a mean to issue a one-cell TABLE element with one cell, with style applied to the outer TABLE element and the inner TD element. For instance, the previous example can be styled as follows, thereby avoiding the outer tabular environment.

\begin{center}\begin{tabular}{c}
\hline \bf English & \bf French \hline
Good Morning & Bonjour \hline
Thank You & Merci \hline
Good Bye & Au Revoir \\
\hline
\end{tabular}\end{center}

9.5.4 Styling the itemize environment

Our idea is highlight lists with a left border whose color fades while lists are nested. Such a design may be appropriate for tables of content, as the one of this document. The text above is typeset from the following \LaTeX\ source.
\begin{toc}
\item Part A
\begin{toc}
\item Chapter I
\begin{toc}
\item Section 1.1
\item Section 1.2
\end{toc}

... \\
\end{toc}
\end{toc}

For simplicity, we assume a limit of four over the nesting depth of toc environment. We first define four style classes toc1, toc2, toc3 and toc4 in the document preamble. Since these classes are similar, a command \newtocstyle is designed.

\newcommand{\newtocstyle}[2]
{\newstyle{\toc#1}{list-style:none;border-left:1ex solid #2;padding:0ex 1ex;}}
\newtocstyle{1}{\getstylecolor{Sepia}}
\newtocstyle{2}{\getstylecolor{Brown}}
\newtocstyle{3}{\getstylecolor{Tan}}
\newtocstyle{4}{\getstylecolor{Melon}}

The toc environment uses a counter to record nesting depth. Notice how the style class of the itemize environment is redefined before \begin{itemize}:

\newcounter{toc}
\newenvironment{toc}
{\stepcounter{toc}\setenvclass{itemize}{toc}{\thetoc}\begin{itemize}}
{\addtocounter{toc}{-1}\end{itemize}}

The outputted HTML is:

\begin{verbatim}
<UL CLASS="toc1">
  <LI CLASS="li-itemize">Part
  <UL CLASS="toc2">
    <LI CLASS="li-itemize">Chapter
    <UL CLASS="toc3">
      <LI CLASS="li-itemize">Section 1.1
      <LI CLASS="li-itemize">Section 1.2
      ...
  </UL>
</UL>
\end{verbatim}

9.6 Miscellaneous

9.6.1 HATQA and style sheets

HAQQA now produces an additional file: a style sheet, which is shared by all the HTML files produced by HAQQA. Please refer to section 7.1 for details.

9.6.2 Producing an external style sheet

By default, style declarations defined with \newstyle go into the header of the HTML document doc.html. However, one can send those declaration into an external style file, whose name is doc.css. Then, HAQQA
automatically relates `doc.html` to its style sheet `doc.css`. To achieve this behavior, it suffices to set the value of the boolean register `externalcss` to `true`, by issuing the command `\externalcss=true` in the preamble of the source document. Notice that HTML output still can be processed by H\TeX\, with correct behavior.

### 9.6.3 Linking to external style sheets

The H\TeX\ command `\loadcssfile{url}` allows the user to link to an external style sheet (like the `LINK` option for HTML). The command takes an `url` of the external sheet as argument and emits the HTML text to `link` to the given external style sheet. As an example, the command

```latex
\loadcssfile{../abc.css}
```

produces the following HTML text in the `<head>` of the document.

```html
    <link rel="stylesheet" type="text/css" href="../abc.css">
```

To yield some effect, `\loadcssfile` must appear in the document preamble. Several `\loadcssfile` commands can be issued. Then the given external style sheets appear in the output, following source order.

Notice that the argument to `\loadcssfile` command is processed. Thus, if it contains special characters such as "\#" or "\$", those must be specified as `\#` and `\$` respectively. A viable alternative would be to quote the argument using the `url` command from the `url` package (see Section B.17.11).

### 9.6.4 Limitations

At the moment, style class definitions cumulate, and appear in the `style` element in the order they are given in the document source. There is no way to cancel the default class definitions performed by H\TeX\ before it starts to process the user's document. Additionally, external style sheets specified with `\loadcssfile` appear before style classes defined with `\newstyle`. As a consequence (if I am right), styles declared by `\newstyle` take precedence over those contained in external style sheets. Thus, using external style sheets, especially if they alter the styling of elements, may produce awkward results.

Those limitations do not apply of course to style classes whose names are new, since there cannot be default definitions for them. Then, linking with external style sheets can prove useful to promote uniform styling of several documents produced by H\TeX\.

## 10 Customizing H\TeX\A

H\TeX\A can be controlled by writing \LaTeX\ code. In this section, we examine how users can change H\TeX\A default behavior or add functionalities. In all this section we assume that a document `doc.tex` is processed, using a private command file `macros.hva`. That is, H\TeX\A is invoked as:

```bash
# hevea macros.hva doc.tex
```

The general idea is as follows: one redefines \LaTeX\ constructs in `macros.hva`, using internal commands. This requires a good working knowledge of both \LaTeX\ and \TeX. Usually, one can avoid internal commands, but then, all command redefinitions interact, sometimes in very nasty ways.

### 10.1 Simple changes

Users can easily change the rendering of some constructs. For instance, assume that all quotations in a text should be emphasized. Then, it suffices to put the following redeclaration in `macros.hva`:

```latex
\renewenvironment{quote}
  {\open{BLOCKQUOTE}\{\style{EM}\}}
  {\close{BLOCKQUOTE}}
```
The same effect can be achieved without using any of the internal commands:

\let\oldquote\quote
\let\oldendquote\endquote
\renewenvironment{quote}{{oldquote}{\em}\{oldendquote}

In some sense, this second solution is easier, when one already knows how to customize \TeX. However, this is less safe, since the definition of \em can be changed elsewhere.

There is yet another solution that takes advantage of style sheets. One can also add this line to the \texttt{macros.hva} file:

\newstyle{quote}{font-style:oblique;}

This works because the environment \texttt{quote} is styled through style class \texttt{quote} (see Section 9.2). Notice that this solution has very little to do with “emphasizing” in the proper sense, since here we short-circuit the implicit path from \em to oblique fonts.

10.2 Changing defaults for type-styles

\texttt{BVA} default rendering of type style changes is described in section B.15.1. For instance, the following example shows the default rendering for the font shapes:

\texttt{itshape \em italic \amp \texttt{slshape slanted \amp \texttt{scshape small caps \amp \texttt{upshape upright \amp \texttt{shape}}}}

By default, \texttt{itshape} is italics, \texttt{slshape} is maroon italics, \texttt{scshape} is small-caps (thanks to style sheets) and \texttt{upshape} is no style at all. All shapes are mutually exclusive, this means that each shape declaration cancels the effect of other active shape declarations. For instance, in the example, small caps shapes is small caps (no italics here).

If one wishes to change the rendering of some of the shapes (say small caps), then one should redefine the old-style \texttt{sc} declaration. For instance, to render small caps as bold fonts, one should redefine \texttt{sc} by \texttt{\renewcommand{\sc}{\texttt{style(B)}}} in \texttt{macros.hva}.

Hence, redefining old-style declarations using internal commands should yield satisfactory output. However, since cancellation is done at the \html level, a declaration belonging to one component may sometimes cancel the effect of another that belongs to another component. Anyway, you might have not noticed it if I had not told you.

10.3 Changing the interface of a command

Assume for instance that the base style of \texttt{doc.tex} is \texttt{jsc} (the \textit{Journal of Symbolic Computation} style for articles). For running \texttt{BVA}, the \texttt{jsc} style can be replaced by \texttt{article} style, but for a few commands whose calling interface is changed. In particular, the \texttt{title} command takes an extra optional argument (which \texttt{BVA} should ignore anyway). However, \texttt{BVA} can process the document as it stands. One solution to insert the following lines into \texttt{macros.hva}:

\texttt{\input{article.hva}}% Force document class 'article'
\let\oldtite=\title
\renewcommand{\title}[2]{{oldtite[#2]}}

The effect is to replace \texttt{\title} by a new command which calls \texttt{BVA} \texttt{\title} with the appropriate argument.
10.4 Checking the optional argument within a command

H\TeX\A fully implements \LaTeX\ \texttt{\newcommand}. That is, users can define commands with an optional argument. Such a feature permits to write a \texttt{\epsfbox} command that has the same interface as the \LaTeX\ command and echoes itself as it is invoked to the \texttt{image} file. To do this, the \TeX\ \texttt{\epsfbox} command has to check whether it is invoked with an optional argument or not. This can be achieved as follows:

\begin{verbatim}
\newcommand{\epsfbox}[2][!*!]{%
  ifthenelse{equal(#1)[!*!]}{
    \begin{tikzpicture}[x=1cm,y=1cm]
      \fill[gray!20] (0,0) rectangle (1,1);
    \end{tikzpicture}
  }{\begin{tikzpicture}[x=1cm,y=1cm]
    \fill[gray!20] (0,0) rectangle (1,1);
  \end{tikzpicture}}%\no optional argument
\end{verbatim}

10.5 Changing the format of images

Semi-automatic generation of included images is described in section 6. Links to included images are generated by the \texttt{\imageflush} command, which calls the \texttt{\imagesrc} command:

\begin{verbatim}
\newcommand{\imageflush}[1][{}]{%# #1 is the image file name
  \begin{tikzpicture}[x=1cm,y=1cm]
    \fill[gray!20] (0,0) rectangle (1,1);
  \end{tikzpicture};\texttt{\imageflush}{}% no optional argument
  \end{verbatim}

That is, you may supply a HTML-style attribute to the included image, as an optional argument to the \texttt{\imageflush} command.

By default, images are PNG images stored in .png files. \TeX\A provides support for the alternative GIF image file format. It suffices to invoke \texttt{hevea} as:

\begin{verbatim}
# hevea gif.hva doc.tex
\end{verbatim}

Then \texttt{imagen} must be run with option \texttt{-gif}:

\begin{verbatim}
# imagen -gif doc
\end{verbatim}

A convenient alternative is to invoke \texttt{hevea} as:

\begin{verbatim}
# hevea -fix gif.hva doc.tex
\end{verbatim}

Then \texttt{hevea} will invoke \texttt{imagen} with the appropriate option when it thinks images need to be rebuild.

10.6 Storing images in a separate directory

By redefining the \texttt{hevea\imagedir} command, users can specify a directory for images. More precisely, if the following redefinition occurs in the document preamble:

\begin{verbatim}
\renewcommand{\hevea\imagedir}{dir}
\end{verbatim}

Then, all links to images in the produced HTML file will be as "dir/...". Then \texttt{imagen} must be invoked with option \texttt{-todir}:

\begin{verbatim}
# imagen -todir dir doc
\end{verbatim}

As usual, \texttt{hevea} will invoke \texttt{imagen} with the appropriate option, provided it is passed the \texttt{-fix} option.

10.7 Controlling imagen from document source

The internal command \texttt{\addimagenopt{option}} adds the text \textit{option} to \textit{imagen} command-line options, when launched automatically by \texttt{hevea} (i.e. when \texttt{hevea} is given the \texttt{-fix} command-line option).

For instance, to instruct \texttt{hevea} to reduce all images by a factor of $\sqrt{2}$, it suffices to state:

\begin{verbatim}
%HEVEA\addimagenopt{-mag 707}
\end{verbatim}

See section C.1.5 for the list of command-line options accepted by \texttt{imagen}.
11 Other output formats

It is possible to translate \LaTeX file into other formats than HTML. There are two such formats: plain text and info files. This enables producing postscript, HTML, plain text and info manuals from one (\LaTeX) input file.

11.1 Text

The \LaTeX file is processed and converted into a plain text formatted file. It allows some pretty-printing in plain text. To translate into text, invoke \TeX as follow:

```
# hevea -t-text [-w <width>] myfile.tex
```

Then, \TeX produces `myfile.txt' a plain text translation of `myfile.tex'.

Additionally, the optional argument \texttt{-w <number>} sets the width of the output for text formatting. By default, the text will be \texttt{72} characters wide.

Nearly every environment has been translated, included lists and tables. The support is nearly the same as in \TeX, except in some cases described hereafter.

Most style changes are ignored, because it is hardly possible to render them in plain text. Thus, there are no italics, bold fonts, underlinings, nor size change or colors... The only exception is for the \texttt{verbatim} environment that puts the text inside quotes, to distinguish it more easily.

Tables with borders are rendered in the same spirit as in \LaTeX. Thus for instance, it is possible to get vertical lines between some columns only. Table rendering can be poor in case of line overflow. The only way to correct this (apart from changing the tables themselves) is to adjust the formatting width, using the \texttt{-w} command-line option.

For now, maths are not supported at all in text mode. You can get very weird results with in-text mathematical formulas. Of course, simple expressions such as subscripts remains readable. For instance, $x^2$ will be rendered as \texttt{x^2}, but \texttt{$\int_0^x f(x)\,dx$} will yield something like \texttt{: int01f(x)dx}.

11.2 Info

The file format info is also supported. Info files are text files with limited hypertext links, they can be read by using \texttt{emacs} info mode or the \texttt{info} program. Please note that \TeX translates plain \LaTeX to info, and not \TeXinfo.

You can translate your \LaTeX files into info file(s) as follows:

```
# hevea -t-info [-w <width>] myfile.tex
```

Then, \TeX produces the file `myfile.info', an info translation of `myfile.tex'. However, if the resulting file is too large, it is cut into pieces automatically, and `myinfo.info' now contains references for all the nodes in the others files, which are named `myfile.info-1, myfile.info-2...'.

The optional argument \texttt{-w} has the same meaning as for text output.

The text will be organized in nodes that follow the pattern of \LaTeX sectioning commands. Menus are created to navigate through the sections easily.

A table of content is produced automatically. References, indexes and footnotes are supported, as they are in HTML mode. However, the info format only allows pointers to info nodes, \textit{i.e.} in \TeX case, to sectional units. As a consequence all cross references lead to sectional unit headers.

46
Part B

Reference manual

This part follows the pattern of the \LaTeX \TeX\ reference manual [\LaTeX, Appendix C].

B.1 Commands and Environments

B.1.1 Command Names and Arguments

\LaTeX\ comments that start with “\%” and end at end of line are ignored and produce no output. Usually, \HVM\ ignore such comments. However, \HVM\ processes text that follows “\%verbatim” and some other comments have a specific meaning to it (see section 5.3).

Command names follow strict \TeX\ syntax. That is, apart from \#, \$, \_, \_ and \^, they either are “\” followed by a single non-letter character or “\” followed by a sequence of letters. Additionally, the letter sequence may be preceded by “@” (and this is the case of many of \HVM\ internal commands), or terminated by “*” (starred variants are implemented as plain commands).

Users are strongly advised to follow strict \TeX\ syntax for arguments. That is, mandatory arguments are enclosed in curly braces \{\ldots\} and braces inside arguments must be properly balanced. Optional arguments are enclosed in square brackets [\ldots]. However, \HVM\ does its best to read arguments even when they are not enclosed in curly braces. Such arguments are a single, different from \“\”, \“\^\” and \“\_\”, character or a command name. Thus, constructs such as \texttt{\textbackslash ec\_ol}, \texttt{\$a\_1\$} or \texttt{\$a\\textbackslash Gamma\$} are recognized and processed as \texttt{\textit{\textbackslash ec\_ol}} \texttt{\textit{a\_1}} and \texttt{\textit{\textbackslash Gamma}}. By contrast, a \texttt{\textbackslash mbox{\ldots}} is not recognized and must be written a \texttt{\textit{\textbackslash mbox{\ldots}}}.

Also note that, by contrast with \LaTeX, comments are parsed during argument scanning, as an important consequence brace nesting is also checked inside comments.

With respect to previous versions, \HVM\ has been improved as regards emulation of complicated argument passing. That is, commands and their arguments can now appear in different static text bodies. As a consequence, \HVM\ correctly processes the following source:

\begin{verbatim}
\newcommand{\boite}{\textbf}
\boite{In bold}
\end{verbatim}

The definition of \texttt{\boite} makes it reduces as \texttt{\textbf} and \HVM\ succeeds in fetching the argument “\texttt{\{In \ bold\}}”. We get

\begin{verbatim}
In bold
\end{verbatim}

The above example arguably is no “legal” \LaTeX, but \HVM\ handles it. Of course, there remains numerous “clever” \LaTeX\ tricks that exploits \TeX\ internal behavior, which \HVM\ does not handle. For instance consider the following source:

\begin{verbatim}
\newcommand{\boite}[1]{\textbf{#1}}
\boite{{In bold}, Not in Bold.}
\end{verbatim}

\LaTeX\ typesets the text “In bold” using bold font, leaving the rest of the text alone. While \HVM\ typesets everything using bold font. Here is \LaTeX\ output:

\begin{verbatim}
In bold, Not in Bold.
\end{verbatim}

Note that, in most similar situations, \HVM\ will likely crash.

As a conclusion of this important section, Users are strongly advised to use ordinary command names and curly braces and not to think too much the \TeX\ way.
B.1.2 Environments

Environment opening and closing is performed like in \LaTeX, with \texttt{\begin{env}} and \texttt{\end{env}}. The *-form of an environment is a plain environment.

It is not advised to use \texttt{\begin{env}} \texttt{\end{env}} in place of \texttt{\begin{env}} \texttt{\end{env}}.

B.1.3 Fragile Commands

Fragile commands are not relevant to \HMA and \texttt{\protect} is defined as a null command.

B.1.4 Declarations

Scope rules are the same as in \LaTeX.

B.1.5 Invisible Commands

I am a bit lost here. However spaces in the output should correspond to users expectations. Note that, to \HMA being invisible commands is a static property attached to command name.

B.1.6 The \texttt{\textbackslash\textbackslash} Command

The \texttt{\textbackslash\textbackslash} and \texttt{\textbackslash\textbackslash} commands are the same, they perform a line break, except inside arrays where they end the current row. Optional arguments to \texttt{\textbackslash\textbackslash} and \texttt{\textbackslash\textbackslash} are ignored.

B.2 The Structure of the Document

Document structure is a bit simplified with respect to \LaTeX, since documents consist of only two parts. The \texttt{preamble} starts as soon as \HMA starts to operate and ends with the \texttt{\begin{document}} construct. Then, any input occurring before \texttt{\end{document}} is translated to HTML. However, the preamble is processed and the preamble comprises the content of the files given as command-line arguments to \HMA, see section C.1.1.1. As a consequence, command and environment definitions that occur before \texttt{\begin{document}} are performed, and they remain valid during all the processing.

In particular, one can define a header and a footer, by using the \texttt{\htmlhead} and \texttt{\htmlfoot} commands in the preamble. These commands register their argument as the header and the footer of the final HTML document. The header appears first while the footer appears last in (visible) HTML output. This is mostly useful when \HMA output is later cut into pieces by \HCR, since both header and footer are replicated at the start and end of any file generated by \HCR. For instance, to append a copyright notice at the end of all the HTML pages, it suffices to invoke the \texttt{\htmlfoot} command as follows in the document preamble:

\begin{verbatim}
\htmlfoot{\copyright to me}
\end{verbatim}

The \texttt{\htmlhead} command cannot be used for changing anything outside of the HTML document body, there are specific commands for doing this. Those command must be used in the document preamble. One can change \HMA default (empty) attribute for the opening \texttt{\textless BODY ... \textgreater } tag by redefining \texttt{@bodyargs}. For instance, you get black text on a white background, when the following declaration occurs before \texttt{\begin{document}}:

\begin{verbatim}
\renewcommand{\@bodyargs}{TEXT=black \texttt{BOCOLOR}=white}
\end{verbatim}

Since version 1.08, a recommended alternative is to use style sheets:

\begin{verbatim}
\newstyle{BODY}{color:black; background:white;}
\end{verbatim}

48
Similarly, some elements can be inserted into the output file \texttt{HEAD} element by redefining the \texttt{\textbackslash meta} command (Such elements typically are \texttt{META}, \texttt{LINK}, etc.). As such text is pure \texttt{HTML}, it should be included in a \texttt{\textasciitilde{html}}} environment. For instance, you can specify author information as follows:

\begin{verbatim}
\\let\\oldmeta=\\meta
\\renewcommand{\\oldmeta}{%\\oldmeta\\begin{html}
\texttt{\textbackslash META name="Author" content="Luc Maranget">\\end{html}}
\end{verbatim}

Note how \texttt{\textbackslash meta} is first bound to \texttt{\textbackslash oldmeta} before being redefined and how \texttt{\textbackslash oldmeta} is invoked in the new definition of \texttt{\textbackslash meta}. Namely, simply overriding the old definition of \texttt{\textbackslash meta} would imply not outputting default meta-information.

The \texttt{\textbackslash charset} command holds the value of the (HTML) document character set. By default, this value is \texttt{\textasciitilde{LATIN1}}. In previous versions of \texttt{HVAR}, one could change the value of the document character set by simply redefining \texttt{\textbackslash charset}. Then, it was users responsibility to provide a \texttt{\textasciitilde{LATEX}}} document in the corresponding encoding. This is no longer true, and users should \textit{not} redefine \texttt{\textbackslash charset} directly. Please, see Section 8.6 for details.

\section{Sentences and Paragraphs}

\subsection{Spacing}

Generally speaking, spaces (and single newline characters) in the source are echoed in the output. Browser then manage with spaces and line-breaks. Following \texttt{\textasciitilde{LATEX}}} behavior, spaces after commands are not echoed. Spaces after invisible commands with arguments are not echoed either.

However this is no longer true in math mode, see section B.7.7 on spaces in math mode.

\subsection{Paragraphs}

New paragraphs are introduced by one blank line or more. Paragraphs are not indented. Thus the macros \texttt{\textbackslash indent} and \texttt{\textbackslash noindent} perform no action. Paragraph are rendered by \texttt{P} elements. In some occasions, this technique may produce spurious paragraphs (see 3.1.1).

\subsection{Footnotes}

The commands \texttt{\textbackslash footnote}, \texttt{\textbackslash footnotetext} and \texttt{\textbackslash footnotemark} (with or without optional arguments) are supported. The \texttt{\textbackslash footnotemark} counter exists and (re)setting it or redefining \texttt{\textbackslash thefootnote} should work properly. When footnotes are issued by a combination of \texttt{\textbackslash footnotemark} and \texttt{\textbackslash footnotetext}, a \texttt{\textbackslash footnotemark} command must be issued first, otherwise some footnotes may get numbered incorrectly or disappear. Footnotes appear at document end in the \textit{article} style and at chapters end in the \textit{book} style. See section 7.3.6 for a description of how footnotes are flushed.

\subsection{Accents and special symbols}

Thanks to Unicode character references, \texttt{HVAR} can virtually output any symbol. It may happen that \texttt{HVAR} does not known about a particular symbol, that is, most of the time, \texttt{HVAR} does not known about a particular command. In that case a warning is issued to draw user attention. Users can then choose a particular symbol amongst the recognized ones, or as an explicit Unicode character reference (see Section 4.2 for an example of this technique).

Commands for making accents used in non-English languages, such as \texttt{\textbackslash o}, work when applied to accent-less (i.e. ascii) letters and that the corresponding accented letters exist in the Unicode character set. Otherwise,
the argument to the command is not modified and a warning is issued. For instance, consider the following source code, where, after a legitimate use of acute accents, one attempt to put an acute accent over the letter “I”:

```
“’École’ works as in \LaTeX, while ‘’h’’ does not.
```

H\TeX\A output will be “École” works as in \LaTeX, while “h” does not. And a warning will be issued.

```
./tmp.tex:3741: Warning: Application of ‘’ on ’h’ failed
```

Observe that using input encodings is a convenient alternative to accent commands — see Section B.17.4.

### B.4 Sectioning

#### B.4.1 Sectioning Commands

Sectioning commands from `\part` down to `\subparagraph` are defined in base style files. They accept an optional argument and have starred versions.

The non-starred sectioning commands from `\part` down to `\subsubsection` show section numbers in sectional units, provided their level is greater than or equal to the current value of the `secnumdepth` counter. Sectional units numbers and the default value of the `secnumdepth` counter are the same as in \LaTeX. Furthermore, given a sectional unit `secname`, the counter `secname` exists and the appearance of sectional units numbers can be changed by redefining `\thesecname`. For instance, the following redefinition turn the numbering of chapters into alphabetic `(uppercase)` style:

\begin{verbatim}
\renewcommand{\thechapter}{\Alph{chapter}}
\end{verbatim}

When jumping to anchors, browsers put the targeted line on top of display. As a consequence, in the following code:

\begin{verbatim}
\section{A section}
\label{section:section}
...
\end{verbatim}

Clicking on the link produced by `\ref{section:section}` will result in \textit{not} displaying the targeted section title. A fix is writing:

\begin{verbatim}
\section{\label{section:section}A section}
...
\end{verbatim}

Note that `\label` should not be be placed last in section title (and I do not know the reason why). Have a try for this section B.4.1!

#### B.4.2 The Appendix

The `\appendix` command exists and should work as in \LaTeX.

#### B.4.3 Table of Contents

H\TeX\A now generates a table of contents, using a procedure similar to the one of \LaTeX\ (a `.htoc` file is involved). One inserts this table of contents in the main document by issuing the command `\tableofcontents`. Table of contents is controlled by the counter `tocdepth`. By default, the table of contents shows sectioning units down to the subsubsection level in \textit{article} style and down to the subsection level in \textit{book} (or \textit{report})
style. To include more or less sectioning units in the table of contents, one should increase or decrease the
\texttt{tocdepth} counter. It is important to notice that \texttt{B\-v\-a\-a} produces such a table of contents, only when it has
total control over cross-references. More precisely, \texttt{B\-v\-a\-a} cannot produce the table of contents when it reads
\texttt{\LaTeX} produced .aux files. Instead, it should read its own .aux files. This will naturally occur if no .aux files are present,
otherwise these .aux files should be deleted, or \texttt{B\-v\-a\-a} should be instructed not to read them
with the command-line option \texttt{-fix} (see Sections B.11.1 and C.1.1.4).

One can also add extra entries in the table of contents by using the command \texttt{\addcontentsline}, in
a way similar to \texttt{\LaTeX} homonymous command. However, hyperlinks need to be introduced explicitly, as
in the following example, where an anchor is defined in the section title and referred to in the argument to
\texttt{\addcontentsline}:

\begin{verbatim}
\subsection*{\name{no:number}{\Use{hacha}}} \\
\addcontentsline{toc}{\subsection}{\ahrefloc{no:number}{\Use{hacha}}} \\
\end{verbatim}

(See Section 8.1.1 for details on commands related to hyperlinks.)

There is no list of figures nor list of tables.

\textbf{Use \texttt{\textit{H\-c\-h\-a\-a}}} 

However, \texttt{B\-v\-a\-a} has a more sophisticated way of producing a kind of map w.r.t. the sectioning of the
document. A later run of \texttt{B\-v\-a\-a} on \texttt{B\-v\-a\-a} output file splits it in smaller files organized in a tree whose
nodes are tables of links. By contrast with \texttt{\LaTeX}, starred sectioning commands generate entries in these
tables of contents. Table of contents entries hold the optional argument to sectioning commands or their
argument when there is no optional argument. Section 7 explains how to control \texttt{B\-v\-a\-a}.

\section{Classes, Packages and Page Styles}

\subsection{Document Class}

Both \texttt{\LaTeX\texttt{2e}} \texttt{\documentclass} and \texttt{\LaTeX} \texttt{\documentclass} are accepted. Their argument \textit{style} is
interpreted by attempting to load a \texttt{style.hva} file. Presently, only the style files \texttt{article.hva}, \texttt{seminar.hva},
\texttt{book.hva} and \texttt{report.hva} exist, the latter two being equivalent.

If one of the recognized styles has already been loaded at the time when \texttt{\documentclass} or \texttt{\documentclass}
is executed, then no attempt to load a style file is made. This allows to override the document style file by
giving one of the four recognized style files of \texttt{B\-v\-a\-a} as a command line argument (see 2.2).

Conversely, if \texttt{B\-v\-a\-a} attempt to load \texttt{style.hva} fails, then a fatal error is flagged, since it can be sure that
the document cannot be processed.

\subsection{Packages and Page Styles}

\texttt{B\-v\-a\-a} reacts to \texttt{\usepackage[options]{pkg}} in the following way:

\begin{enumerate}
  \item The whole \texttt{\usepackage} command with its arguments gets echoed to the \textit{image} file (see 6).
  \item \texttt{B\-v\-a\-a} attempt to load file \texttt{pkg.hva}, (see section C.1.1.1 on where \texttt{B\-v\-a\-a} searches for files).
\end{enumerate}

Note that \texttt{B\-v\-a\-a} will not fail if it cannot load \texttt{pkg.hva} and that no warning is issued in that case.

The \texttt{B\-v\-a\-a} distribution contains implementations of some packages, such as \texttt{verbatim}, \texttt{colors}, \texttt{graphics},
etc. 

In some situations it may not hurt all if \texttt{B\-v\-a\-a} does not implement a package, for instance \texttt{B\-v\-a\-a} does
not provide an implementation for the \texttt{fullpage} package.

Users needing an implementation of a package that is widely used and available are encouraged to contact
the author. Experienced users may find it fun to attempt to write package implementations by themselves.
B.5.3 The Title Page and Abstract

All title related commands exist, with the following peculiarities:

- The argument to the \title command appears in the HTML document header. As a consequence, titles should remain simple. Normal design (as regards BAWA) is for \title to occur in the document preamble, so that the title is known at the time when the document header is emitted (while processing \begin{document}). However, there are two subtleties.

  If no \title command occurs in document preamble and that one \title command appears in the document, then the title is saved into the .aux file for a next run of BAWA to put it in the HTML document header.

  If \title commands are present both in preamble and after \begin{document}, then the former takes precedence.

- When not present the date is left empty. The \today command generates will work properly only if \hevea is invoked with the -exec xxdate.exe option. Otherwise \today generates nothing and a warning is issued.

The abstract environment is present is all base styles, including the book style. The titlepage environment does nothing.

B.6 Displayed Paragraphs

Displayed-paragraph environments translate to block-level elements.

In addition to the environments described in this section, BAWA implements the \center, \flushleft and \flushright environments. BAWA also implements the corespondant \TeXX style declaration \texttt{\begin{centering} \centering \raggedright and \raggedleft}, but these declarations may not work as expected, when they do not appear directly inside a displayed-paragraph environment or inside an array element.

B.6.1 Quotation and Verse

The quote and quotation environments are the same thing: they translate to \texttt{\begin{blockquote}} elements. The verse environment is not supported.

B.6.2 List-Making environments

The \itemize, \enumerate and \description environments translate to the \texttt{UL}, \texttt{OL}, and \texttt{DL} elements and this is the whole story.

As a consequence, no control is allowed on the appearances of these environments. More precisely optional arguments to \item do not function properly inside \itemize and \enumerate. Moreover, item labels inside \itemize or numbering style inside \enumerate are browser dependent.

However, customized lists can be produced by using the the \texttt{list} environment (see next section).

B.6.3 The list and \texttt{trivlist} environments

The list environment translates to the \texttt{DL} element. Arguments to \texttt{\begin{list}} are handled as follows:

\texttt{\begin{list}{\texttt{default\_label}\{decs\}}}

The first argument \texttt{default\_label} is the label generated by an \item command with no argument. The second argument, \texttt{decs} is a sequence of declarations. In practice, the following declarations are relevant:

\texttt{\usecounter{counter}} The counter \texttt{counter} is incremented by \texttt{\refstepcounter} by every \item command with no argument, before it does anything else.
\renewcommand{\makelabel}{[1]}{...} The command \item executes \makelabel{label}, where label is the item label, to print its label. Thus, users can change label formatting by redefining \makelabel. The default definition of \makelabel simply echoes label.

As an example, a list with an user-defined counter can be defined as follows:

\newcounter{couna}
\begin{list}{\{the\couna\}}{
\item \usecounter{couna}%
\renewcommand{\makelabel}{[1]}{\textbf{\#1}.}}
\end{list}

This yields:
1. First item.
2. Second item.

The \texttt{trivlist} environment is also supported. It is equivalent to the \texttt{description} environment.

\subsection{Verbatim}

The \texttt{verbatim} and \texttt{verbatim*} environments translate to the \texttt{PRE} element. Inside \texttt{verbatim*}, spaces are replaced by underscores ("_\_").

Similarly, \texttt{verb} and \texttt{verb*} translate to the \texttt{CODE} text element.

The \texttt{alltt} environment is supported.

\section{Mathematical Formulae}

\subsection{Math Mode Environment}

The three ways to use math mode ($...$, \(\ldots\)) and \begin{math}...\end{math} are supported. The three ways to use display math mode ($$...$$, \[\ldots\] and \begin{displaymath}...\end{displaymath} are also supported. Furthermore, \texttt{ensuremath} behaves as expected.

The \texttt{equation}, \texttt{eqnarray}, \texttt{eqnarray*} environments are supported. Equation labeling and numbering is performed in the first two environments, using the \texttt{equation} counter. Additionally, numbering can be suppressed in one row of an \texttt{eqnarray}, using the \texttt{\nonumber} command.

Math mode is not as powerful in \texttt{HVMa} as in \texttt{LATEX}. The limitations of math mode can often be surpassed by using math display mode. As a matter of fact, math mode is for in-text formulas. From the \texttt{HTML} point of view, this means that math mode does not close the current flow of text and that formulas in math mode must be rendered using text-level elements only. By contrast, displayed formulas can be rendered using block-level elements. This means that \texttt{HVMa} have much more possibilities in display context than inside normal flow of text. In particular, stacking text elements one above the over is possible only in display context.

\subsection{Common Structures}

\texttt{HVMa} admits, subscript (_), superscripts (^) and fractions (\texttt{\frac{num\{er\}}{den\{om\}}}). The best effect is obtained in display mode, where \texttt{HTML} \texttt{TABLE} element is extensively used. By contrast, when not in display mode, \texttt{HVMa} uses only \texttt{SUB} and \texttt{SUP} text-level elements to render superscripts and subscript, and the result may not be very satisfying.

However, simple subscripts and superscripts, such as \texttt{x\_i} or \texttt{x^2}, are always rendered using the \texttt{SUB} and \texttt{SUP} text-level elements and their appearance should be correct even in in-text formulas.
When occurring outside math mode, characters _ and ^ act as ordinary characters and get echoed to the output. However, a warning is issued.

An attempt is made to render all ellipsis constructs (\ldots, \cdots, \vdots and \ddots). The effect may be strange for the latter two.

B.7.3 Square Root

The \( n \)th root command \( \sqrt[n]{x} \) is supported only for \( n=3,4 \), thanks to the existence of Unicode characters for the same. For the others, we shift to fractional exponents, in which case, the \( \sqrt[n]{x} \) command is defined as follows:

\[
\text{newcommand}\{\sqrt[n]{x}\} [\left(\frac{x}{n}\right)^{\frac{1}{n}}]
\]

B.7.4 Unicode and mathematical symbols

The support for unicode symbols offered by modern browsers allows to translate almost all math symbols correctly.

Log-like functions and variable sized-symbols are recognized and their subscripts and superscripts are put where they should in display mode. Subscript and superscript placement can be changed using the \limits and \nolimits commands. Big delimiters are also handled.

B.7.5 Putting one thing above/below/inside

The commands \texte{stackrel}, \underline and \overline are recognized. They produce sensible output in display mode. In text mode, these macros call the \texte{stackrel}, \underline and \overline macros. These macros perform the following default actions

\texte{stackrel} Performs ordinary superscripting.

\underline Underlines its argument, using the \texte{u} text-level element.

\overline Overlines using style-sheets (used <SPAN> with a top border).

The command \boxed works well both in display and normal math mode. Input of the form \boxed{\frac{\pi}{2}} produces \( \frac{\pi}{2} \) in normal math, and

\[
\frac{\pi}{2}
\]

in display-math mode. The commands \texte{big}, \texte{biggr} etc. are also rendered well. Some examples can be found in the test file random-math.html provided with the distribution.

B.7.6 Math accents

Math accents that have corresponding text accents (\hat, \tilde, etc.) are handled by default. They in fact act as the corresponding text-mode accents (Section B.3.4). As a consequence, they work properly only on ascii letters. This may be quite cumbersome, but at least some warnings draw user’s attention on the problem. If accents are critical to your document and that H\TeX{\footnote{H\TeX{ provides a solution to redefine the math accent command. A suggested replacement is using limit superscripts. That way accents are positioned above symbols in display mode and after symbols in text mode.}} issues a lot of warnings, a solution is to redefine the math accent command. A suggested replacement is using limit superscripts. That way accents are positioned above symbols in display mode and after symbols in text mode.

\text{newcommand}\{\hat[1]{\text{hat}}\} [\hat{\text{hat}}]\]

\text{newcommand}\{\mathop[\#1]{\\text{mathop}}} [\mathop[\#1]\]

\text{newcommand}\{\limits^\{\text{limits}\} [\limits^\{\text{limits}\}\]

\text{newcommand}\{\textasciicircum[\text{asciicircum}} [\textasciicircum[\text{asciicircum}]

Displayed:

$$
\text{Displayed:}
$$

54
The $\vec{u}$ command is rendered differently in display and non-display mode. In display mode, the arrow appears in normal position, while in non-display the arrow appears as an ordinary superscript.

\[ \vec{u} \text{ in text mode: } \vec{u} \quad \text{in display mode: } \vec{u} \]

Most "extensible accents" (\texttt{\wideremove}, \texttt{\widehat}, etc.) are not even defined. There are a few exceptions:

- line "accents":
  \begin{align*}
  \text{\underline{abc}} & \quad \text{\underline{abc}} \\
  \text{\overline{1 \times 2 \times \cdots \times n}} & \quad \text{\overline{1 \times 2 \times \cdots \times n}}
  \end{align*}

- Brace "accents":
  \begin{align*}
  \text{\underbrace{1 \times 2 \times \cdots \times n}} & \quad \text{\overbrace{1 \times 2 \times \cdots \times n}}
  \end{align*}

- And arrow "accents":
  \begin{align*}
  \text{\overleftarrow{1 \times 2 \times \cdots \times n}} & \quad \text{\rightarrow{1 \times 2 \times \cdots \times n}}
  \end{align*}

B.7.7 Spacing

By contrast with \LaTeX, space in the input matters in math mode. One or more spaces are translated to one space. Furthermore, spaces after commands (such as \texttt{\alpha}) are echoed except for invisible commands (such as \texttt{\tt}). This allows users to control space in their formulas, output being near to what can be expected.

Explicit spacing commands (\texttt{\!, \:, \; and \;}) are recognized, the first two commands do nothing, while the others output one space.

B.7.8 Changing Style

Letters are italicized inside math mode and this cannot be changed. The appearance of other symbols can be changed using \LaTeX style changing commands (\texttt{\mathbf}, etc.). The commands \texttt{\boldmath} and \texttt{\unboldmath} are not recognized. Whether symbols belonging to the symbol font are affected by style changes or not is browser dependent.

The \texttt{\textit} declaration and the \texttt{\mathit} command (that yield calligraphic letters in \LaTeX) exist. They yield red letters by default.

Observe that this does not corresponds directly to how \LaTeX manage style in math mode and that, in fact, style cannot really change in math mode.

Math style changing declarations \texttt{\displaystyle} and \texttt{\textstyle} do nothing when \HWA is already in the requested mode, otherwise they issue a warning. This is so because \HWA implements displayed maths as tables, which require to be both opened and closed and introduce line breaks in the output. As a consequence, warnings on \texttt{\displaystyle} are to be taken seriously.

The commands \texttt{\scriptstyle} and \texttt{\scriptscriptstyle} perform type size changes.

B.8 Definitions, Numbering

B.8.1 Defining Commands

\HWA understands command definitions given in \LaTeX style. Such definitions are made using \texttt{\newcommand}, \texttt{\renewcommand} and \texttt{\providecommand}. These three constructs accept the same arguments and have the same meaning as in \LaTeX, in particular it is possible to define an user command with one optional argument. However, \HWA is more tolerant: if command \texttt{name} already exists, then a subsequent \texttt{\newcommand{\textit{name}}}... is
ignored. If macro \texttt{name} does not exist, then \texttt{\textbackslash renewcommand\{name\}}... performs a definition of \texttt{name}. In both cases, \LaTeX{} would crash, \texttt{\textbackslash HMA} just issues warnings.

The behavior of \texttt{\textbackslash newcommand} allows to shadow document definition, provided the new definitions are processed before the document definitions. This is easily done by grouping the shadowing definition in a specific style file given as an argument to \texttt{\textbackslash HMA} (see section 5.1). Conversely, changes of base macros (i.e. the ones that \texttt{\textbackslash HMA} defines before loading any user-specified file) must be performed using \texttt{\textbackslash renewcommand}.

Scoping rules apply to macros, as they do in \LaTeX{}. Environments and groups define a scope and command definition are local to the scope they occur.

It is worth noticing that \texttt{\textbackslash HMA} also partly implements \TeX{} definitions (using \texttt{\textbackslash def} and bindings (using \texttt{\textbackslash let}), see section B.16.1 for details.

\subsection{Defining Environments}

\texttt{\textbackslash HMA} accepts environment definitions and redefinitions by \texttt{\textbackslash newenvironment} and \texttt{\textbackslash renewenvironment}. The support is complete and should conform to [\LaTeX{} Sections C.8.2].

Environments define a scope both for commands and environment definitions.

\subsection{Theorem-like Environments}

New theorem-like environments can also be introduced and redefined, using \texttt{\textbackslash newtheorem} and \texttt{\textbackslash renewtheorem}.

Note that, by contrast with plain environments definitions, theorem-like environment definitions are global definitions.

\subsection{Numbering}

\LaTeX{} counters are (fully ?) supported. In particular, defining a counter \texttt{cmd} with \texttt{\textbackslash newcounter\{cmd\}} creates a macro \texttt{\textbackslash thecmd} that outputs the counter value. Then the \texttt{\textbackslash thecmd} command can be redefined. For instance, section numbering can be turned into alphabetic style by:

\texttt{\textbackslash renewcommand\{\textbackslash thesection\}\{\textbackslash alph\{section\}\}}

Note that \TeX{} style for counters is not supported at all and that using this style will clobber the output. However, \texttt{\textbackslash HMA} implements the \texttt{calc} package that makes using \TeX{} style for counters useless in most situations (see section B.17.3).

\subsection{The ifthen Package}

The \texttt{ifthen} package is partially supported. The one unsupported construct is the \texttt{\textbackslash lengthtest} test expression, which is undefined.

As a consequence, \texttt{\textbackslash HMA} accepts the following example from the \LaTeX{} manual:

\texttt{\newcounter\{ca\}\newcounter\{cb\}\%}
\texttt{\newcommand\{\textbackslash printgcd\}\{2\}\%}
\texttt{\setcounter\{ca\}\{#1\}\setcounter\{cb\}\{#2\}\%}
\texttt{Gcd\(#1,#2\) =}
\texttt{\\texttt{\textbackslash whileof\not\{value\{ca\} = value\{cb\}\}\%}
\texttt{\{ifthenelse\{value\{ca\} > value\{cb\}\}\%}
\texttt{\{addtocounter\{ca\}\{-value\{cb\}\}\%}
\texttt{\{addtocounter\{cb\}\{-value\{ca\}\}\%}
\texttt{gcd\{\textbackslash arabic\{ca\}, \textbackslash arabic\{cb\}\} = \%}
\texttt{\textbackslash arabic\{ca\}\%}
\texttt{For example: \textbackslash printgcd\{54\}\{30\}}

\begin{flushright}
56
\end{flushright}
For example: $\gcd(54, 30) = \gcd(24, 30) = \gcd(24, 6) = \gcd(18, 6) = \gcd(12, 6) = \gcd(6, 6) = 6$.

Additionally, a few boolean registers are defined by \HMA. Some of them are of interest to users.

\texttt{hevea} Initial value is \texttt{true}. The \texttt{hevea.sty} style file also defines this register with initial value \texttt{false}.

\texttt{mmode} This register value reflects \HMA operating mode, it is \texttt{true} in math-mode and \texttt{false} otherwise.

\texttt{display} This register value reflects \HMA operating mode, it is \texttt{true} in display-mode and \texttt{false} otherwise.

\texttt{footer} Initial value is \texttt{true}. When set false, \HMA does not insert its footer "This document has been translated by \HMA".

Finally, note that \HMA also recognized à la \LaTeX conditional macros (see section B.16.1.4). Such macros are fully compatible with the boolean registers of the \texttt{ifthen} package, as it is the case in \LaTeX.

\section{Figures and Other Floating Bodies}

Figures and tables are put where they appear in source, regardless of their placement arguments. They are outputted inside a \texttt{BLOCKQUOTE} element and they are separated from enclosing text by two horizontal rules.

Captions and cross referencing are handled. However captions are not moved at end of figures: instead, they appear where the \texttt{caption} commands occur in source code. The \texttt{supressfloats} command does nothing and the figure related counters (such as \texttt{topnumber}) exist but are useless.

Marginal notes are handled in \HMA specific way. By default, all notes go in the right margin. Issuing \texttt{reversemarginpar} causes the notes to go in the left margin. Unsurprisingly, issuing \texttt{normalmarginpar} returns to default behavior.

The \texttt{marginpar} command has an optional argument.

\begin{verbatim}
\texttt{\marginpar[left\_text]{right\_text}}
\end{verbatim}

If optional argument \texttt{left\_text} is present and that notes go in the left margin, then \texttt{left\_text} is the text of the note. Otherwise, \texttt{right\_text} is the text of the note. As a conclusion, marginal notes in \HMA always go to a fixed side of the page, which side being controlled by the commands \texttt{normalmarginpar} (right side) and \texttt{reversemarginpar} (left side). This departs form \LaTeX that selects a default side depending on the parity of the page counter.

Marginal notes are styled by the means of two environment style classes (see Section 9.3) : \texttt{marginpar} and \texttt{marginparside}. The latter \texttt{marginparside} takes care of margins and placement as a float, its value is \texttt{marginparright} for notes in the right margin and \texttt{marginparleft} for notes in the left margin. Users are not expected to alter those. The \texttt{marginpar} environment style class governs the general aspect of all marginal notes. Users can control the aspect of all marginal notes by defining a new style class and assigning the \texttt{marginpar} environment style class. For instance, to get all marginal notes in red font, and taking 10\% of the page width (in place of the default 20\%), one can issue the following commands in the document preamble.

\begin{verbatim}
\newstyle{.mynote}{width:10\%; color:red;}
\setenvclass{marginpar}{.mynote}
\end{verbatim}

\section{Lining It Up in Columns}

\subsection{The tabbing Environment}

Limited support is offered. The \texttt{tabbing} environment translate to a flexible \texttt{tabular}-like environment. Inside this environment, the command \texttt{\kill} ends a row, while commands \texttt{\=} and \texttt{\>} start a new column. All other tabbing commands do not even exist.
B.10.2 The array and tabular environments

These environments are supported, using HTML TABLE element, rendering is satisfactory in most (not too complicated) cases. By contrast with \LaTeX, some of the array items always are typeset in display mode. Whether an array item is typeset in display mode or not depends upon its column specification, the l, c and r specifications open display mode while the remaining p and \& do not. The l, c, r and \& specifications disable word wrap, while the p specification enables it.

Entries in a column whose specification is l (resp. c or r) get left-aligned (resp. centered or right-aligned) in the horizontal direction. They will get top-aligned in the vertical direction if there are other column specifications in the same array that specify vertical alignment constraints (such as p{wd}, see below). Otherwise, vertical alignment is unspecified.

Entries in a column whose specification is p{wd} get left-aligned in the horizontal direction and top-aligned in the vertical direction and a paragraph break reduces to one line break inside them. This is the only occasion where \hvea makes a distinction between LR-mode and paragraph mode. Also observe that the length argument wd to the p specification is ignored.

Some \LaTeX array features are not supported at all:

- Optional arguments to \begin{array} and \begin{tabular} are ignored.
- The command \vline does not exist.

Some others are partly rendered:

- Spacing between columns is different.
- \& formatting specifications in \multicolumn argument are ignored.
- If a l appears somewhere in the column formatting specification, then the array is shown with borders.
- The command \hline does nothing if the array has borders (see above). Otherwise, an horizontal rule is outputed.
- The command \vline ignores its argument and is equivalent to \hline.
- Similarly the command \extracolsep issues a warning and ignores its argument.

Additionally, the \texttt{tabular*} environment is recognized and gets rendered as an HTML table with an advisory width attribute.

By default, \hvea implements the \texttt{array} package (see \LaTeX-bis, Section 5.3) and section B.17.2 in this document, which significantly extends the \texttt{array} and \texttt{tabular} environments.

B.11 Moving Information Around

B.11.1 Files

In some situations, \hvea uses some of the ancillary files generated by \LaTeX. More precisely, while processing file \texttt{doc.tex}, the following files may be read:

- \texttt{.aux} The file \texttt{doc.aux} contains cross-referencing information, such as figure or section numbers. If this file is present, \hvea reads it and put such numbers (or labels) inside the links generated by the \texttt{\ref} command. If the \texttt{.aux} file is not present, or if the \texttt{hvea} command is given the \texttt{-fix} option, \hvea will instead use \texttt{.haux} files.
- \texttt{.haux} Such files are \hvea equivalents of \texttt{.aux} files. Indeed, they are \texttt{.aux} files tailored to \hvea needs. Two runs of \hvea might be needed to get cross references right.
.htoc This file contains a formatted table of contents. It is produced while reading the .haux file. As a consequence a table of contents is available only when the .haux file is read.

.hbl The doc.hbl file is generated by bblhva from doc.haux. When present, it is read by the \bibliography command.

.bl The doc.bl file is generated by Bif\TeX{} from doc.aux. When present, and if no doc.bl exists, doc.bl is read by the \bibliography command.

.hidx and .hind B\TeX{} computes its own indexes, using .hidx files for storing index references and, using .hind files for storing formatted indexes. Index formatting significantly departs from the one of Bif\TeX{}.

B\TeX{} does not fail when it cannot find an auxiliary file. When another run of B\TeX{} is needed, a warning is issued, and it is user's responsibility to run B\TeX{} again, several runs of B\TeX{} might be needed to get indexes right.

B.11.1.2 Cross-References

The \LaTeX{} \texttt{\label} and \texttt{\ref} are changed by B\TeX{} into HTML anchors and local links. Spaces in the arguments to these commands are better avoided.

Additionally, numerical references to sectional units, figures, tables, etc. are shown, as they would appear in the .dvi file. Numerical references to pages (such as generated by \texttt{\pageref}) are not shown; only an link is generated.

While processing a document \texttt{doc.tex}, cross-referencing information can be computed in two different, mutually exclusive, ways, depending on whether \LaTeX{} has been previously run or not:

- If there exists a file \texttt{doc.aux}, then cross-referencing information is extracted from that file. Of course, the \texttt{doc.aux} file has to be up-to-date, that is, it should be generated by running \LaTeX{} as many times as necessary. (For B\TeX{} needs, one run is probably sufficient.)

- If no \texttt{doc.aux} file exists, then B\TeX{} expect to find cross-referencing information in the file \texttt{doc.haux}.

When using its own \texttt{doc.haux} file, B\TeX{} will output a new \texttt{doc.haux} file at the end of its processing. This new \texttt{doc.haux} file contains actualized cross referencing information. Hence, in that case, B\TeX{} may need to run twice to get cross-references right. Note that, just like \LaTeX{}, B\TeX{} issues a warning then the cross-referencing information it generates differs from what it has read at start-up, and that it does not fail if \texttt{doc.haux} does not exist.

Observe that if a non-correct \texttt{doc.aux} file is present, then cross-references will apparently be wrong. However the links are correct.

B.11.3 Bibliography and Citations

The \texttt{\cite} macro is supported. Its optional argument is correctly handled. Citation labels are extracted from the .aux file if present, from the .haux file otherwise. Note that these labels are put there by \LaTeX{} in the first case, and by B\TeX{} in the second case, when they process the \texttt{\bibitem} command.

Using Bif\TeX{}

All Bif\TeX{} related commands exist and echo the appropriate information into the .haux file.

In particular, the \texttt{\bibliography} command exists and attempts to load the formatted bibliography, i.e. to load the .hbl file. The .hbl file is produced from the .haux file by the companion program bblhva (see C.1.4). To include the bibliographic references extracted from .bib databases, it should normally suffice to do:

59
In case no .bbl file exists, the \bibliography command attempts to load the .bib file normally used while combining \LaTeX\ and \BibTeX. Thus, another way to extract bibliographic references from .bib databases is:

```
# latex doc.tex
# bibtex doc
# hevea doc.tex
```

In case both files exist, notice that loading the .bbl file has priority over loading the .bib file.

### B.11.4 Splitting the Input

The \input and \include commands exist and they perform exactly the same operation of searching (and then processing) a file, whose name is given as an argument. See section C.1.1.1 on how \Hevea searches files. However, in the case of the \include command, the file is searched only when previously given as an argument to the \includeonly command.

Note the following features:

- \TeX\ syntax for \input is not supported. That is, one should write \input{filename}.

- If filename is excluded with the -e command-line option (see section C.1.1.4), then \Hevea does not attempt to load filename. Instead, it echoes \input{filename} and \include{filename} commands into the image file. This sounds complicated, but this is what you want!

- \Hevea does not fail when it cannot find a file, it just issues a warning.

The \listfiles command is a null command.

### B.11.5 Index and Glossary

Glossaries are not handled (who uses them?).

While processing a document doc.tex, index entries go into the file doc.idx, while the formatted index gets written into the file doc.indx. As with \LaTeX, two runs of \Hevea are normally needed to format the index. However, if all index producing commands (normally \index) occur before the index formatting command (normally \printindex), then only one run is needed.

As in \LaTeX, index processing is not enabled by default and some package has to be loaded explicitly in the document preamble. To that aim, \Hevea provides the standard package makeidx, and two extended packages that allow the production of several indexes (see section B.17.7).

Formatting of indexes in \Hevea departs from \LaTeX\ behavior. More precisely the theindex environment does not exist. Instead, indexes are formatted using special indexenv environments. Those details do not normally concern users. However, the number of columns in the presentation of the index can be controled by setting the value of the indexcols counter (default value is two).

### B.11.6 Terminal Input and Output

The \typeout command echos its argument on the terminal, macro parameter #i are replaced by their values. The \typein command is not supported.
B.12 Line and Page Breaking

B.12.1 Line Breaking

The advisory line breaking command \linebreak will produce a line break if it has no argument or if its optional argument is 4. The \nolinebreak command is a null command.

The \ and \* commands output a <BR> tag, except inside arrays where the close the current row. Their optional argument is ignored. The \newline command outputs a <BR> tag.

All other line breaking commands, declarations or environments are silently ignored.

B.12.2 Page Breaking

They are no pages in the physical sense in HTML. Thus, all these commands are ignored.

B.13 Lengths, Spaces and Boxes

B.13.1 Length

All length commands are ignored, things go smoothly when \hsize syntax is used (using the \newlength, \settowidth etc. commands, which are null macros). Of course, if lengths are really important to the document, rendering will be poor.

Note that \hsize length syntax is not at all recognized. As a consequence, writing things like \textwidth=10cm will clobber the output. Users can correct such misbehavior by adopting \hsize syntax, here they should write \settowidth{\textwidth}{10cm}.

B.13.2 Space

The \hspace, \vspace and \addvspace spacing commands and their starred versions recognize positive explicit length arguments. Such arguments get converted to a number of non-breaking spaces or line breaks. Basically, the value of \em or \em is one space or one line-break. For other length units, a simple conversion based upon a 10pt font is used.

\hsize cannot interpret more complicated length arguments or perform negative spacing. In these situations, a warning is issued and no output is done.

Spacing commands without arguments are recognized. The \enspace, \quad and \qqquad commands output one, two and four non-breaking spaces, while the \smallskip, \medskip and \bigskip output one, one and two line breaks.

Stretchable lengths do not exist, thus the \hfill and \vfill macros are undefined.

B.13.3 Boxes

Box contents is typeset in text mode (i.e. non-math and non-display mode). Both \hsize boxing commands \mbox and \makebox commands exist. However \makebox generates a specific warning, since \hsize ignore the length and positioning instructions given as optional argument.

Similarly, the boxing with frame \fbox and \framebox commands are recognized and \framebox issues a warning. When in display mode, \fbox frames its argument by enclosing it in a table with borders. Otherwise, \fbox calls the \textfbox command, which issues a warning and typesets its argument inside a \mbox (and thus no frame is drawn). Users can alter the behavior of \fbox in non-display mode by redefining \textfbox.

Boxes can be saved for latter usage by storing them in bins. New bins are defined by \newsavebox{cmd}.

Then some text can be saved into cmd by \mbox{cmd}{text} or \begin{lrbox}{cmd} text \end{lrbox}. The text is translated to HTML, as if it was inside a \mbox and the resulting output is stored. It is retrieved
(and outputted) by the command \usebox{cmd}. The \savebox command reduces to \abox, ignoring its optional arguments. The \rule commands translate to a HTML horizontal rule (<hr>) regardless of its arguments. All other box-related commands do not exist.

B.14 Pictures and Colors

B.14.1 The picture environment and the graphics Package

It is possible to have pictures and graphics processed by imagen (see section 6.1). In the case of the picture environment it remains users responsibility to explicitly choose source chunks that will get rendered as images. In the case of the commands from the graphics package, this choice is made by \HWA.

For instance consider the following picture:

\newcommand{\cms}{
\setlength{\unitlength}{1mm}
\begin{picture}(50,10)
\put(0,7){\makebox(0,0)[b]{\cms}}
\multiput(10,7)(10,0){5}{\addtocounter{cms}{1}\makebox(0,0)[b]{\arabic{cms}}}
\multiput(1,0)(1,0){49}{\line(0,1){2.5}}
\multiput(5,0)(10,0){5}{\line(0,1){5}}
\thicklines
\put(0,0){\line(1,0){50}}
\multiput(0,0)(10,0){6}{\line(0,1){5}}
\end{picture}

Users should enclose all picture elements in a \imagine environment (or inside %BEGIN IMAGE ... %END IMAGE comments) and insert an \imageflush command, where they want the image to appear in HTML output:

%BEGIN IMAGE
\newcommand{\cms}{
\setlength{\unitlength}{1mm}
\begin{picture}(50,10)
...
\end{picture}
%END IMAGE
%HEVEA\imageflush

This will result in normal processing by \LaTeX\ and image inclusion by \HWA:

\begin{center}
\scalebox{.5}{\includegraphics{round.ps}}
\scalebox{.75}{\includegraphics{round.ps}}
\includegraphics{round.ps}
\end{center}

All commands from the graphics package are implemented using the automatic image inclusion feature. More precisely, the outermost invocations of the \includegraphics, \scalebox, etc. commands are sent to the image image file and there will be one image per outermost invocation of these commands. For instance, consider a document doc.tex that loads the graphics package and that includes some (scaled) images by:

\begin{center}
\scalebox{.5}{\includegraphics{round.ps}}
\scalebox{.75}{\includegraphics{round.ps}}
\includegraphics{round.ps}
\end{center}
Then, issuing the following two commands:

```latex
\# hevea doc.tex
\# imagen doc
```

yields HTML that basically consists in three image links, the images being generated by imagen. Since the advent of pdflatex, using `\includegraphics` to insert bitmap images (e.g. `.gif` or `.jpg`) became frequent. In that case, users are advised not to use \TeX\!\TeX\!\LaTeX\, default implementation of the `graphics` package. Instead, they may use a simple variation of the technique described in Section 8.2.

### B.14.2 The color Package

\TeX\!\TeX\!\LaTeX\, partly implements the `color` package. Implemented commands are `\definecolor`, `\color`, `\colorbox` and `\textcolor`. Other commands from the `color` package do not exist. At startup, colors black, white, red, green, blue, cyan, yellow and magenta are pre-defined.

Colors are defined by `\definecolor{name}{model}{spec}`, where `name` is the color name, `model` is the color model used, and `spec` is the color specification according to the given model. Defined colors are used by the declaration `\color{name}` and by the command `\textcolor{name}{text}`, which change text color. Please note that, the `\color` declaration accepts color specifications directly when invoked as `\color{model}{spec}`. The `\textcolor` command has a similar feature.

As regards color models, \TeX\!\TeX\!\LaTeX\, implements the rgb, cmyk, hsv and hls color models. In those models, color specifications are floating point numbers less than one. For instance, here is the definition for the red color:

```latex
\definecolor{red}{rgb}{1, 0, 0}
```

The `named` color model is also supported, in this model color specification are just names... Named colors are the ones of dvips.

GreenYellow, Yellow, Goldenrod, Dandelion, Apricot, Peach, Melon, YellowOrange, Orange, BurntOrange, Bittersweet, RedOrange, Mahogany, Maroon, BrickRed, Red, OrangeRed, RubyRed, WildStrawberry, Salmon, CarnationPink, Magenta, VioletRed, Rhodamine, Mulberry, RedViolet, Fuchsia, Lavender, Thistle, Orchid, DarkOrchid, Purple, Plum, Violet, RoyalPurple, BlueViolet, Periwinkle, CadetBlue, CornflowerBlue, MidnightBlue, NavyBlue, RoyalBlue, Blue, Cerulean, Cyan, ProcessBlue, SkyBlue, Turquoise, TealBlue, Aquamarine, BlueGreen, Emerald, JungleGreen, SeaGreen, Green, ForestGreen, PineGreen, LimeGreen, YellowGreen, SpringGreen, OliveGreen, RawSienna, Sepia, Brown, Tan, Gray, Black, White.

There are at least three ways to use colors from the `named` model.

1. Define a color name for them.
2. Specify the named color model as an optional argument to `\color` and `\textcolor`.
3. Use the names directly (\TeX\!\TeX\!\LaTeX\, implements the `color` package with the `usenames` option given).

That is:

1. `\definecolor{rouge-brique}{named}{BrickRed}` `\textcolor{rouge-brique}{Text as a brick}.`
2. `\textcolor{named}{BrickRed}{Text as another brick}.`
3. `\textcolor{BrickRed}{Text as another brick}.`

Colors should be used carefully. Too many colors hinders clarity and some of the colors may not be readable on the document background color.
B.14.2.1 The \texttt{bgcolor} environment

With respect to the \texttt{Em} color package, \texttt{HVM} features an additional \texttt{bgcolor} environment, for changing the background color of some subparts of the document. The \texttt{bgcolor} environment is a displayed environment and it normally starts a new line. Simple usage is \texttt{\begin{bgcolor}\{color\}\ldots\end{bgcolor}}, where \texttt{color} is a color defined with \texttt{\definecolor}. Hence the following source yield a paragraph with a red background:

\begin{verbatim}
\begin{bgcolor}\{red\}
\color{yellow}Yellow letters on a red background
\end{bgcolor}
\end{verbatim}

The \texttt{bgcolor} environment is implemented by a \texttt{TABLE} element, it takes an optional argument that is used as an attribute for this \texttt{TABLE} element (default value is \texttt{CELLPADDING=10}). For instance, the following source:

\begin{verbatim}
\begin{bgcolor}[CELLPADDING=0]\{yellow\}
\color{red}Red letters on a yellow background
\end{bgcolor}
\end{verbatim}

will be typeset on a yellow background and without padding.

B.14.2.2 From High-Level Colors to Low-Level Colors

High-level colors are color names defined with \texttt{\definecolor}. Low-level colors are \texttt{HTML}-style colors. That is, they are either one of the sixteen conventional colors black, silver etc., or a RGB hexadecimal color specification of the form \texttt{"\#XXXXXX"}. One changes the high-level \texttt{high-color} into a low-level color by \texttt{\getcolor\{high-color\}}. Low-level colors are appropriate inside \texttt{HTML} attributes and as arguments to the \texttt{\fontcolor} internal macro. An example of \texttt{\getcolor} usage can be found at the end of section 8.5.

There is also \texttt{\getstylecolor} command that acts like \texttt{\getcolor}, except that it does not output the double quotes around RGB hexadecimal color specifications. Such low-level colors are appropriate for style definitions in cascading style sheets [CSS-2]. See Section 9.3 for an example.

B.15 Font Selection

B.15.1 Changing the Type Style

All \texttt{Em} declarations and environments for changing type style are recognized. Aspect is rather like \texttt{EM} output, but there is no guarantee.

As \texttt{HTML} does not provide the same variety of type styles as \texttt{Em}, some type style get rendered by using colors. For instance, the slanted shape yields maroon italics. Here is how \texttt{HVM} implements text-style declarations by default:

\begin{verbatim}
\itshape italics  \ttfamily typewriter font  \bfseries bold
\slshape maroon italics \sffamily purple    \mdseries no style
\scshape small caps \rmfamily no style
\upshape no style       \end{verbatim}

Text-style commands also exists, they are defined as \texttt{\box\{\texttt{decl}..\}}. For instance, \texttt{\texttttt} is defined as a command with one argument whose body is \texttt{\box\{\ttfamily#1\}}. Finally, the \texttt{\emph} command for emphasized text also exists.

As in \texttt{Em}, type styles consists in three components: \texttt{shape}, \texttt{series} and \texttt{family}. However this distinction does not exist in \texttt{HTML}: one specifies a type style and that's all. \texttt{HVM} implements the three components by making one declaration to cancel the effect of other declarations of the same kind.

64
Old style declarations are also recognized, they translate to text-level elements. However, no elements are canceled when using old style declaration. Thus, the source “\sl\acs{slanted} and \smallcaps{small caps}” yields maroon “slanted” small caps. Users need probably not worry about this. However this has an important practical consequence: to change the default rendering of type styles, one should redefine old style declaration in order to benefit from the cancelation mechanism. See section 10.2 for a more thorough description.

**B.15.2 Changing the Type Size**

All declarations, from `\tiny` to `\huge` are recognized. Output is not satisfactory inside headers elements generated by sectioning commands.

**B.15.3 Special Symbols**

The `\symbol{num}` outputs character number `num` (decimal) from the Unicode character set. This departs from \TeX, which output symbol number `num` in the current font.

**B.16 Extra Features**

This section describes \Hevea functionalities that extends on plain \LaTeX, as defined in \LaTEX. Most of the features described here are performed by default.

**B.16.1 \TeX macros**

Normally, \Hevea does not recognize constructs that are specific to \TeX. However, some of the internal commands of \Hevea are homonymous to \TeX macros, in order to enhance compatibility. Note that full compatibility with \TeX is not guaranteed.

**B.16.1.1 À la \TeX macros definitions**

The `\def` construct for defining commands is supported. It is important to notice that \Hevea semantics for `\def` follows \TeX semantics. That is, defining a command that already exists with `\def` succeeds.

Delimiting characters in command definition are somehow supported. Consider the following example from the \TeX Book:

\begin{verbatim}
\def\Look{\textsc{Look}}
\def\x{\textsc{x}}
\def\cs \#1#2\$\{\#3}c\}#2\$
\cs\AB{\Look}{\textsc{And}}\x{\textsc{look}}\$5.
\end{verbatim}

It yields: And $\textsc{look}ab\textsc{Look}\textsc{Look}\textsc{cx}5$.

Please note that delimiting characters are supported as far as I could, problems are likely with delimiting characters which include spaces or command names, in particular the command name `\{. One can include `\{ in a command argument by using the grouping characters `\( ...

\begin{verbatim}
\def\frenchquote {\guillemotleft \emph{#1} \guillemotright} (in French)
he said \frenchquote{\guillemotleft \emph{f} ? \guillemotright} (in French).
\end{verbatim}

Yields: he said « \emph{Alors cette accolade ouvrante \textquoteleft \textquoteleft \textquoteleft f \textquoteleft \textquoteleft ?} » (in French).

Another issue regards comments: “\%” in arguments may give undefined behaviors, while comments are better avoided while defining macros. As an example, the following code will not be handled properly by \Hevea:

\begin{verbatim}
\def\x\%
  #1{y}
\end{verbatim}
Such \TeX source should be rewritten as \texttt{\textbackslash def \#1\{y\}}.

Another source of incompatibility with \TeX is that substitution of macros parameters is not performed at the same moment by \HVM and \TeX. However, things should go smoothly at the first level of macro expansion, that is when the delimiters appear in source code at the same level as the macro that is to parse them. For instance, the following source will give different results in \TeX and in HVM:

\begin{verbatim}
\def \cs#1{\texttt{#1}}
\def \othercs#1{\cs#1}
\othercs{\texttt{coucou}}
\end{verbatim}

\TeX output is “\texttt{coucou}”, while HVM output is “\texttt{coucou}”. Here is \TeX output: “\texttt{coucou}”. Please note that in most situations this discrepancy will make \HVM crash.

### B.16.1.2 The \textbackslash let construct

\HVM also processes a limited version of \texttt{\let}:

\begin{verbatim}
\let \macroname1 = \macroname2
\end{verbatim}

The effect is to bind \macroname1 to whatever \macroname2 is bound to at the time \texttt{\let} is processed. This construct may prove very useful in situations where one wishes to slightly modify basic commands. See sections 10.3 and B.2 for examples of using \texttt{\let} in such a situation.

### B.16.1.3 The \textbackslash global construct

It is possible to escape scope and to make global definitions and bindings by using the \TeX construct \texttt{\global}. The \texttt{\global} construct is significant before \texttt{\def} and \texttt{\let} constructs.

Also note that \texttt{\newdef} is equivalent to \texttt{\global\def}.

### B.16.1.4 \TeX Conditional Macros

The \texttt{\newif} if \texttt{name}, where \texttt{name} is made of letters only, creates three macros: \texttt{\ifname}, \texttt{name\true} and \texttt{name\false}. The latter two set the \texttt{name} condition to \texttt{true} and \texttt{false}, respectively. The \texttt{\ifname} command tests the condition \texttt{name}:

\begin{verbatim}
\ifname text1 \else text2 \fi
\end{verbatim}

Text \texttt{text1} is processed when \texttt{name} is \texttt{true}, otherwise \texttt{text2} is processed. If \texttt{text2} is empty, then the \texttt{\else} keyword can be omitted.

Note that \HVM also implements \TeX ifthen package and that \TeX simple conditional macros are fully compatible with \TeX boolean registers. More precisely, we have the following correspondences:

<table>
<thead>
<tr>
<th>\TeX</th>
<th>\UTeX</th>
</tr>
</thead>
<tbody>
<tr>
<td>\newif\texttt{name}</td>
<td>\newboolean{\texttt{name}}</td>
</tr>
<tr>
<td>\texttt{name\true}</td>
<td>\setboolean{\texttt{name}}{\texttt{true}}</td>
</tr>
<tr>
<td>\texttt{name\false}</td>
<td>\setboolean{\texttt{name}}{\texttt{false}}</td>
</tr>
<tr>
<td>\texttt{\ifname text1\else text2\fi}</td>
<td>\texttt{\ifthenelse{\boolean{\texttt{name}}}{\texttt{text1}} {\texttt{text2}}}</td>
</tr>
</tbody>
</table>
B.16.1.5 Other \TeX\ Macros

\HVM\A\ implements the macros \unskip and \endinput. It also supports the \csname...\endcsname construct.

B.16.2 Command Definition inside Command Definition

If one strictly follows the \TeX\ manual, only commands with no arguments can be defined inside other commands. Parameters (i.e. \texttt{#n}) occurring inside command bodies refer to the outer definition, even when they appear in nested command definitions. That is, the following source:

\newcommand{\outercom}{[1]{\newcommand{\insidecom}{[#1]\insidecom}}}
\outercom{outer}

yields this output:

\begin{verbatim}
outer
\end{verbatim}

Nevertheless, nested commands with arguments are allowed. Standard parameters \texttt{#n} still refer to the outer definition, while nested parameters \texttt{##n} refer to the inner definition. That is, the source:

\newcommand{\outercom}{[1]{\newcommand{\insidecom}{[1][#1]\insidecom{inner}}}}
\outercom{outer}

yields this output:

\begin{verbatim}
inner
\end{verbatim}

B.16.3 Date and time

Date and time support is not enabled by default, for portability and simplicity reasons.

However, \HVM\A\ source distribution includes a simple (sh) shell script \texttt{xdate.exe} that activates date and time support. The \texttt{hevea} command, should be invoked as:

\# hevea -exec xdate.exe ...

This will execute the script \texttt{xdate.exe}, whose output is then read by \HVM\A\. As a consequence, standard \TeX\ counters \texttt{year}, \texttt{month}, \texttt{day} and \texttt{time} are defined and \TeX\ command \texttt{\today} works properly. Additionally the following counters and commands are defined:

<table>
<thead>
<tr>
<th>Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{weekday}</td>
<td>day of week, 0...6</td>
</tr>
<tr>
<td>\texttt{Hour}</td>
<td>hour, 00...11</td>
</tr>
<tr>
<td>\texttt{hour}</td>
<td>hour, 00...23</td>
</tr>
<tr>
<td>\texttt{minute}</td>
<td>minute, 00...59</td>
</tr>
<tr>
<td>\texttt{second}</td>
<td>second, 00...61 (According to date man page!)</td>
</tr>
</tbody>
</table>

Command \texttt{\am} AM or PM
Command \texttt{\timezone} Time zone
Command \texttt{\xdate} Output of the date Unix command

Note that I chose to add an extra option (and not an extra \texttt{\exec} primitive) for security reasons. You certainly do not want to enable \HVM\A\ to execute silently an arbitrary program without being conscious of that fact. Moreover, the \texttt{hevea} program does not execute \texttt{xdate.exe} by default since it is difficult to write such a script in a portable manner.

Windows users should enjoy the same features with the version of \texttt{xdate.exe} included in the Win32 distribution.

67
B.16.4 Fancy sectioning commands

Loading the fancysection.hva file will radically change the style of sectional units headers: they appear over a green background, the background color saturation decreases as the sectioning commands themselves do. Additionally, the document background color is white.

Note: Fancy section has been re-implemented using style-sheets. While it respects the old behavior, users are encouraged to try out style-sheets for more flexibility. See Section 9 for details.

The fancysection.hva file is intended to be loaded after the document base style. Thus, to use fancy section style in doc.tex whose base style is article you should issue the command:

    # hevea article.hva fancysection.hva doc.tex

You can also make a doc.hva file that contains the two lines:

    \input{article.hva}
    \input{fancysection.hva}

And then launch hevea as:

    # hevea doc.hva doc.tex

Sectioning command background colors can be changed by redefining the corresponding colors (part, chapter, section,...). For instance, you get various mixes of red and orange by:

    \input{article.hva}
    \input{fancysection.hva}
    \definecolor{part}{named}{BrickRed}
    \definecolor{section}{named}{RedOrange}
    \definecolor{subsection}{named}{BurntOrange}

(See section B.14.2 for details on the named color model that is used above.)

Another choice is issuing the command \colorsections{hue}, where hue is a hue value to be interpreted in the HSV model. For instance,

    \input{article.hva}
    \input{fancysection.hva}
    \colorsections{20}

will yield sectional headers on a red-orange background.

B.16.5 Targetting Windows

At the time of this release, Windows support for symbols through Unicode is not as complete as the one of Linux, which I am using for testing H\WA.

One of the most salient shortcomings is the inability to display sub-elements for big brackets, braces and parenthesis, which H\WA normally outputs when it processes \left[ \right] etc.

We (hopefully) expect Windows fonts to display more of Unicode easily in a foreseeable future. As a temporary fix, we provide a style file winfonts.hva. Authors concerned by producing pages that do not look too ugly when viewed through Windows browsers are thus advised to load the file winfonts.hva. For instance they can invoke H\WA as:

    # hevea winfonts.hva ...

At the moment, loading winfonts.hva only changes the rendering of $\LaTeX$ big delimiters, avoiding the troublesome Unicode entities.

More generally, it remains authors responsibility to be careful not to issue too refined Unicode entities. To that aim, authors that target a wide audience should first limit themselves to the most common symbols (e.g. use \leq \leq in place of \preceq \preceq) and, above all, they should control the rendering of their documents using several browsers.
B.16.6 \texttt{HV\$\$A} as a Back-End for VideoC

HV\$\$A is one of the back-ends of the VideoC system for producing educational CDROM to teach programming languages. VideoC author is Christian Queinnec and the documentation is available at:

VideoC translates \LaTeX{} source into a variety of formats, including \texttt{html}. VideoC source may contain some special constructs for typesetting source code or to annotate text in sophisticated ways. HV\$\$A internal engine implements some of the core constructs needed by VideoC. The rest of VideoC constructs are implemented by the \texttt{.hva} files from VideoC distribution.

B.17 Implemented Packages

HV\$\$A distribution includes \texttt{.hva} packages that are implementations of \LaTeX{} packages. Packages described in the "Blue Book" (\texttt{makeidx}, \texttt{ifthen}, \texttt{graphics}—and \texttt{graphicx}—, \texttt{color}, \texttt{alltt}) are provided. Additionally, quite a few extra packages are provided. I provide no full documentation for these packages, users should refer to the first pages of the package documentation, which can usually be found in the book \cite{latex-bis}, in your local \LaTeX{} installation or in a TeX CTAN-archive.

At the moment, most package options are ignored, except for the \texttt{babel} package, where it is essential.

B.17.1 AMS compatibility

HV\$\$A \texttt{amsmath} package defines some of the constructs of the \texttt{amsmath} package. At the moment, supported constructs are the \texttt{cases} environment and matrix environments \cite{latex-bis, Section 8.4}, the environments for multi-line displayed equations (\texttt{gather}, \texttt{split}, …) \cite{latex-bis, Section 8.5} and the \texttt{numberwithin} command \cite{latex-bis, Section 8.6.2}.

HV\$\$A provides support for the \texttt{amssymb} symbols using Unicode. I found Unicode equivalent for most symbols. However, a few symbols remain undefined (e.g. \texttt{\warsubsetneqq}).

B.17.2 The \texttt{array} and \texttt{tabularx} packages

The \texttt{array} package is described in \cite{latex-bis, Section 5.3} and in the local documentation of modern \LaTeX{} installations. It is a compatible extension of \LaTeX{} \texttt{array} (see B.10.2). Basically, it provides new column specifications and a \texttt{\newcolumntype} construct for user-defined column specifications. Table 1 gives a summary of the new column specifications and of how HV\$\$A implements them.

Note that \texttt{centered}, \texttt{top-aligned} or \texttt{bottom-aligned} in the vertical direction, do not have exactly the same meaning in \LaTeX{} and in \texttt{html}. However, the aspect is the same when all columns agree w.r.t. vertical alignment. Ordinary column types (\texttt{c}, \texttt{l} and \texttt{r}) do not specify vertical alignment, which therefore becomes browser dependent.

The \texttt{\{decl\}} and \texttt{\{deel\}} constructs permit the encoding of \LaTeX{} \texttt{\cases} macro as follows:

\begin{verbatim}
def \cases#1\{\left\begin{array}{\{1>{\{1}<\{1}\#1\end{array}\right.\}
\end{verbatim}

(This is an excerpt of the \texttt{latexcommon.hva} file.)

New column specifications are defined by the \texttt{\newcolumntype} construct:

\begin{verbatim}
\newcolumntype{co}{\narg} {body}
\end{verbatim}

Where \texttt{co} is one letter, the optional \texttt{narg} is a number (defaults to 0), and \texttt{body} is built up with valid column specifications and macro-argument references (\texttt{#int}). Examples are:
Table 1: Column specifications from the array package

| \texttt{m\{width\}} | Equivalent to the \texttt{p} column specification (the \texttt{width} argument is ignored, entries are typeset in paragraph mode with paragraph breaks being reduced to a single line break), except that the entries are centered vertically. |
| \texttt{b\{width\}} | Equivalent to the \texttt{p} column specification, except that the entries are bottom-aligned vertically. |
| \texttt{>{decl}} | Can be used before \texttt{1, c, r, p(\ldots)}, \texttt{m(\ldots)} or \texttt{b(\ldots)}. It inserts \texttt{decl} in front of the entries in the corresponding column. |
| \texttt{<{decl}} | Can be used after \texttt{1, c, r, p(\ldots)}, \texttt{m(\ldots)} or \texttt{b(\ldots)}. It inserts \texttt{decl} after entries in the corresponding column. |
| \texttt{!{decl}} | Equivalent to \texttt{@{decl}}. |

\begin{verbatim}
\newcolumntype{C}{>{\bf c}}
\newcolumntype{E}{|[\{#1\}c|}}
\begin{tabular}{CE|c}
\hline
one & two & three & four \ \hline
five & six & seven & eight \ \hline
\end{tabular}
\end{verbatim}

The column specification \texttt{C} means that entries will be typeset centered and using bold font, while the column specifications \texttt{E(num)} stands for \textit{num} centered columns. We get:

\begin{verbatim}
one two three four
five six seven eight
\end{verbatim}

HVA implements column specifications with commands defined in the \texttt{newcommand} style. Thus, they have the same behavior as regards double definition, which is not performed and induces a warning message. Thus, a column specification that is first defined in a macro.hva specific file, overrides the document definition.

The \texttt{tabularx} package [\texttt{\LaTeX}-bis, Section 5.3.5] provides a new tabular environment \texttt{tabularx} and a new column type \texttt{X}. HVA makes the former equivalent to \texttt{tabular} and the latter equivalent to \texttt{p(ignored)}. By contrast with the subtle array formatting that the \texttt{tabularx} package performs, this may seem a crude implementation. However, rendering is usually correct, although different.

More generally and from the HTML point of view such sophisticated formatting is browser job in the first place. However, the HTML definition allows suggested widths or heights for table entries and table themselves. From HVA point of view, drawing the border line between what can be specified and what can be left to the browser is not obvious at all. At the moment HVA choice is not to specify too much (in particular, all length arguments, either to column specifications or to the arrays themselves, are ignored). As a consequence, the final, browser viewed, aspect of arrays will usually be different from their printed aspect.

\textbf{B.17.3 The \texttt{calc} package}

The \texttt{calc} package enables using traditional, infix, notation for arithmetic operations inside the \texttt{num} argument to the \texttt{\setcounter{name}\{num\}} and \texttt{\addtocounter{name}\{num\}} constructs (see [\texttt{\LaTeX}-bis, Section A.4].)

The \texttt{calc} package provides a similar extension of the syntax of the \texttt{len} argument to the \texttt{\setlength} and \texttt{\addtolength} constructs. HVA does not implement this extension, since it does not implement length registers in the first place.
B.17.4 Specifying the document input encoding, the `inputenc` package

The `inputenc` package enables \LaTeX{} to process a file according to various 8-bit encodings, plus UTF-8. The one used encoding is specified as an option while loading the package `\usepackage[encoding]{inputenc}`. At the moment, \LaTeX{} recognizes ten Latin encodings (from latin1 to latin10), the ko18-r encoding, the ascii encoding, four windows encodings, the applemac encoding, and the utf8 encoding. It is important to notice that loading the `inputenc` package alters the HTML document charset. For instance if the `latin9` input encoding is selected by:

```
\usepackage[latin9]{inputenc}
```

Then, the document charset is ISO-8859-15, which is an enhanced version of ISO-8859-1 with some characters for E, e and €. The rationale behind changing the output document charset at the same time as changing the input encoding is to allow non-ascii bytes in the input file to be replicated as themselves in the output file.

However, one can change the document charset (and the output translator) by using the internal command `\def\charset{US-ASCII}`. For instance, one can specify `latin1` encoding, while producing HTML pages in ascii:

```
\usepackage[latin1]{inputenc}
\def\charset{US-ASCII}
```

See section 8.6 for a more thorough description of HTML charset management.

The `inputenc` package also provides the command `\inputencoding{encoding}` that changes the input encoding at any time. The argument `encoding` can be any of the options accepted by `\usepackage[encoding]{inputenc}`. The command `\inputencoding` of \LaTeX{} follows the behavior of its \TeX{} counterpart, it the sense that it obeys scope rules. Notice that `\inputencoding` does not change the document output encoding and charset.

B.17.5 More symbols

\LaTeX{} implements the following packages: `latexsym amsmath, textcomp (a.k.a. “Text companion”) and `eurosym (a nice € symbol in \LaTeX{}).

B.17.6 The `comment` package

The `comment` package provides two commands, `\excludecomment` and `\includecomment`, for (re-)defining new environments that ignore their content or that do nothing. The comment environment is also defined as an environment of the first kind.

B.17.7 Multiple Indexes with the `index` and `multind` packages

\LaTeX{} supports several simultaneous indexes, following the scheme of the `index` package, which is present in modern \TeX{} distributions. This scheme is backward compatible with the standard indexing scheme of \TeX{}.

Support is not complete, but the most useful commands are available. More precisely, \LaTeX{} knows the following commands:

```
\newindex{tag}{ext}{ignored}{indexname} Declare an index. The first argument `tag` is a tag to select this index in other commands; `ext` is the extension of the index information file generated by \LaTeX{} (e.g., `idx`); `ignored` is ignored by \LaTeX{}; and `indexname` is the title of the index. There also exists a `\renewindex` command that takes the same arguments and that can be used to redefine previously declared indexes.

\makeindex Perform `\newindex{default}{idx}{ind}{Index}`.
```

71
\index{tag}{any} Act as the \LaTeX \index command except that the information extracted from \texttt{arg} goes to the \texttt{tag} index. The \texttt{tag} argument defaults to default, thereby yielding standard \LaTeX behavior for the \index command without an optional argument. There also exists a starred-variant \texttt{\index*} that additionally typesets \texttt{arg}.

\printindex{tag} Compute, format and output index whose \texttt{tag} is \texttt{tag}. The \texttt{tag} argument defaults to default.

The \texttt{multind} package is supported to some extend, but \texttt{index} is definitely to be preferred.

## B.17.8 “Natural” bibliographies, the \texttt{natbib} package

\LaTeX version of \texttt{natbib}\footnote{http://www.ctan.org/tex-archive/help/Catalogue/entries/natbib.html} is present in modern installations.

Implementation is quite complete and compatible with version 8.0 of the \texttt{natbib} package (with the \texttt{keyval} style command \texttt{setcitestyle}).

Unimplemented features are the sorting and compression of references. Automatic generation of an index of citations is handled, but the current implementation probably is quite fragile.

## B.17.9 Multiple bibliographies

The \texttt{multibib} package

\BibTeX provides a slightly incomplete implementation of the \texttt{multibib} package. The one non-implemented feature is the simultaneous definition of more than one bibliography. That is one cannot invoke \texttt{\newcites} as follows:

\begin{verbatim}
\newcites{suf1, suf2}{Title1, Title2}
\end{verbatim}

Instead, one should perform to calls to the \texttt{\newcites} command:

\begin{verbatim}
\newcites{suf1}{Title1}\newcites{suf2}{Title2}
\end{verbatim}

The \texttt{chapterbib} package

A basic implementation is provided. At the moment, you can define one bibliography per included file and no toplevel bibliography. \BibTeX implementation of this package recognizes the option \texttt{sectionbib} and provides the command \texttt{\sectionbib} to change the sectioning command introduced by bibliographies.

## B.17.10 Support for babel

### B.17.10.1 Basics

\BibTeX offers support for the \LaTeX package \texttt{babel}. When it reads the command

\begin{verbatim}
\usepackage[lang-list]{babel}
\end{verbatim}

it loads \texttt{babel.hva}, and sends it the saved \texttt{lang-list}. The file \texttt{babel.hva} then looks at each language (say \texttt{x}) in it, and loads \texttt{x.hva}, which offers support for the language \texttt{x}. As in \LaTeX, the last language in the list is selected as default. As an example the command

\begin{verbatim}
\usepackage[english,french,german]{babel}
\end{verbatim}

would load \texttt{babel.hva}, then the files \texttt{english.hva}, \texttt{french.hva}, \texttt{german.hva} containing the respective definitions, and finally activate the definitions in \texttt{german.hva} and sets the current language to \texttt{german}.
B.17.10.2 Commands and languages

The following babel commands for changing and querying the language work as in \LaTeX:

1. \selectlanguage: to change the language

2. \iflanguage: to branch after comparing with current language

The language specific details are described in the corresponding .hva file, just as in the .sty file for \LaTeX. Users need to supply this file for their language, or modify/check the files if they are already supplied with the distribution. The list of languages is given below.

<table>
<thead>
<tr>
<th>Language</th>
<th>Language</th>
<th>Language</th>
<th>Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>american</td>
<td>australian</td>
<td>brazil</td>
<td>catalan</td>
</tr>
<tr>
<td>check</td>
<td>croatian</td>
<td>danish</td>
<td>dutch</td>
</tr>
<tr>
<td>english</td>
<td>esperanto</td>
<td>finnish</td>
<td>french</td>
</tr>
<tr>
<td>galician</td>
<td>german</td>
<td>italian</td>
<td>magyar</td>
</tr>
<tr>
<td>norsk</td>
<td>nynorsk</td>
<td>polish</td>
<td>portuges</td>
</tr>
<tr>
<td>romanian</td>
<td>russian</td>
<td>slovak</td>
<td>slovene</td>
</tr>
<tr>
<td>spanish</td>
<td>swedish</td>
<td>turkish</td>
<td></td>
</tr>
</tbody>
</table>

B.17.10.3 Writing .hva files

The languages for which .hva files are available with the distribution are English, French, German, Austrian and Czech. These may need to be modified as not all accents and hyphenation techniques are supported.

They can be written/modified as simple \TeX files (see the section B.16.1.1 on writing \TeX macros for details). As an example, one may also take a look at the file french.hva\(^3\), which describes the details for French.

Note how all definitions are inside the definition for \texttt{\selectlanguage{french}}, which is the command that \texttt{\selectlanguage{french}} would call. Similar commands need to be provided (i.e. \texttt{x@babel in \texttt{x.hva for language x}}).

Some definitions may involve specifying Unicode characters, for doing so, using the \texttt{\@printu} is recommended (cf. Section 8.3). The definition of Unicode characters can be found at http://www.unicode.org/charts/\(^4\). Most language specific Unicode characters can be found in the first few files.

B.17.11 The \url package

\LaTeX source\(^5\).

This package in fact provides a enhanced \verb|\url| command that can appear inside other command arguments. This command is named \texttt{\url}, but it can be used for any verbatim text, including DOS-like path names. Hence, one can insert urls in one's document without worrying about \LaTeX active characters:

This is a complicated url: \url{http://foo.com/"user#label%coucou}. which gets typeset as: “This is a complicated url: http://foo.com/"user#label%coucou.”

The main use for the \url command is to specify urls as arguments to \H VA commands for hyperlinks (see section 8.1.1):

\url{http://hevea.inria.fr/}

It yields: “\H VA home page is http://hevea.inria.fr/”.

However the \url command is fragile, as a consequence it cannot be used inside \texttt{\footnote} first argument (This is a \LaTeX problem, not an \H VA one). The \url package solves this problem by providing the \texttt{\urldef} command for defining commands whose body is typeset by using \texttt{\url}:

\url{http://www.ctan.org/tex-archive/help/Catalogue/entries/url.html}

\(^3\) http://html/french.hva

\(^4\) http://www.unicode.org/charts/

Such a source defines the robust command \texttt{\heveahome} as the intended url. Hence the following source works as expected:

\url{\heveahome}{\heveahome}{\hevea} home page

It yields: “Have a look at \heveahome home page”.

Using \texttt{\url} inside command definitions with a \texttt{#i} argument is a bad idea, since it gives “verbatim” a rather random meaning. Unfortunately, in some situations (e.g., no \texttt{%, no \#}), it may work in \LaTeX. By contrast, it does not work in \HVMa. In such situations, \texttt{\urldef} should be used.

\HVMa implementation is somehow compatible at the “programming level”. Thus, users can define new commands whose argument is understood verbatim. The \texttt{\urlhref.hva} style file from the distribution takes advantage of this to define the \texttt{\url} command, so that it both typesets an url and inserts a link to it. The \texttt{\urlhref.hva} style file (which is an \HVMa style file and not a \LaTeX style file) can be adequate for bibliographic references, which often use \texttt{\url} for its typesetting power. Of course, loading \texttt{\urlhref.hva} only makes sense when all arguments to \texttt{\url} are urls...

\section{Verbatim text: the \texttt{moreverb} and \texttt{verbatim} packages}

These two packages provide new commands and environments for processing verbatim text. I recommend using \texttt{moreverb} rather than \texttt{verbatim}, since \HVMa implementation is more advanced for the former package.

\section{Typesetting computer languages: the \texttt{listings} package}

I strongly recommend the \texttt{listings} package. Learning the user interface requires a little effort, but it is worth it.

\HVMa features a quite compatible implementation, please refer to the original package documentation. Do not hesitate to report discrepancies. Note that \HVMa does not produce very compact HTML in case you use this package. This can be cured by giving \texttt{hevea} the command-line option -U (see C.1.1.4).

The \texttt{listlisting} environment is styled through an homonymous style class (see 9.2 and 9.3) and most \texttt{listlisting} environments get translated to DIV elements with the appropriate \texttt{\getenvclass\texttt{listlisting}} class, which, by default is \texttt{listlisting}. A few points deserve mention:

1. The definition of default style class \texttt{listlisting} includes the important declarations \texttt{font-family:monospace;} and \texttt{white-space:pre;} which, more or less, specify non-proportional font and mandatory line breaks. In case you replace \texttt{listlisting} by another style class (by \texttt{\getenvclass\texttt{listlisting}}\texttt{(another one)}), your alternate definition should probably feature an identical specification. Otherwise, rendering would be poor, as regards spacing and line breaks.

2. When listings are framed, that is, when some \texttt{frame=}... or \texttt{background=}... keyval specifications are active, they no longer get translated to DIV elements. Instead they get translated to one cell tables whose TD and TABLE elements are styled through style classes \texttt{listlisting} and \texttt{listframe}, respectively. Of course, those two style classes follow the usual \texttt{\getenvclass\texttt{getenvclass}} mechanism. That way, one can for instance center all framed listings by issuing the following declaration in the document preamble:

\texttt{\newstyle{.listframe}{margin:auto;}}

Notice that the default style class \texttt{listframe} is empty.

\url{http://hevea.inria.fr/}
3. Unfortunately the `white-space: pre` style declaration is still a bit young, and some browsers implement it in rather uncomplete fashion. This is particularly true as regards text copy-pasted from browser display. In case you want to provide your readers with easy copy-paste of listings, you can, by issuing the command `\lstavoidswhitepre` in the document preamble. Then, `white-space: pre;` is not used any longer: spaces get rendered by non-breaking space entities and linebreaks by `<br>` elements, which significantly increase output size. However, as a positive consequence, display remains correct and text copy-pasted from browser display indeed possesses the linebreaks shown in display.

### B.17.14 (Non-)Multipage tabular material

These two packages provide \LaTeX\ users with the possibility to typeset tabular material over several pages [\LaTeX\-bis, Section 5.4]. Of course, \HvA\ does not care much about physical pages. Thus the supertabular and longtable environments are rendered more or less as tabular environments inside table environments.

#### B.17.15 Typesetting inference rules: the \texttt{mathpartir} package

The \texttt{mathpartir} package, authored by D. Rémy, essentially provides two features:

1. An environment \texttt{mathpar} for typesetting a sequence of math formulas in mixed horizontal and vertical mode. The environment selects the best arrangement according to the line width, exactly as paragraph mode does for words.

2. A command `\inferrule` (and its starred variant) for typesetting inferences rules.

We give a short description, focussing on \HvA-related details. Users are encouraged to refer to the original documentation\footnote{\url{http://pauillac.inria.fr/~remy/latex/index.html#tir}} of the package.

In the following, comments on rule typesetting apply to \HvA\ output and not to \LaTeX\ output.

#### B.17.15.1 The \texttt{mathpar} environment

In its \LaTeX\ version, the \texttt{mathpar} environment is a “paragraph mode for formulas”. It allows to typeset long list of formulas putting as many as possible on the same line:

```latex
\begin{mathpar}
A \text{-- Formula} \hspace{1cm} A \text{-- Formula} \\
\text{Longer} \text{-- Formula} \hspace{1cm} \text{Longer} \text{-- Formula} \\
\text{And} \hspace{1cm} \text{And}
\text{The} \text{-- Last} \text{-- One} \hspace{1cm} \text{The} \text{-- Last} \text{-- One}
\end{mathpar}
```

In the example above, formulas are separated with `\text{and}`. The \LaTeX\ implementation also changes the meaning of paragraph breaks (either explicit as a `\par` command or implicit as a blank line) to act as `\text{and}`. It also redefines the command `\text{\textbackslash as an explicit line-break in the flow of formulas.}

```latex
\begin{mathpar}
\int_0^2 x \,dx = \frac{3}{2}
\text{\textbackslash}
\int_0^3 x \,dx = \frac{5}{2}
\end{mathpar}
```

\[ \int_0^2 x \,dx = \frac{3}{2} \]
\[ \int_0^3 x \,dx = \frac{5}{2} \]
The \LaTeX{} version is simplistic: Formulas are typeset in math display mode, \texttt{and} separators always produce horizontal space, while \texttt{\&} always produce line-breaks. However, when prefixed by \texttt{\&va} the meaning of explicit separators is inverted: that is, \texttt{\&va\&} produces a line-break, while \texttt{\&va\&} produces horizontal space. Hence, we can typeset the previous example on two lines:

\begin{verbatim}
\begin{mathpar}
A - Formula \texttt{\&and}
Longer - Formula \texttt{\&va\&and}
And \texttt{\&and The - Last - One}
\end{mathpar}
\end{verbatim}

It is to be noticed that the \TeX{} version of the package defines \texttt{\&va} as a no-op, so as to allow explicit instructions given to \TeX{} not to impact on the automatic typesetting performed by \TeX{}.

B.17.15.2 The \texttt{infrule} macro

The \texttt{infrule} macro is designed to typeset inference rules. It should only be used in math mode (or display math mode). It takes three arguments, the first being optional, specifying the label, premises, and conclusions respectively. The premises and the conclusions are both lists of formulas, and are separated by \texttt{\&}. A simple example of its use is

\begin{verbatim}
\begin{infrule}
  [label]
  \{one \& two \& three \& or \& more \& premises\}
  \{and \& any \& number \& of \& conclusions \& as \& well\}
\end{infrule}
\end{verbatim}

which gives the following rendering:

\[
\text{\begin{tabular}{lllll}
  LABEL & one & two & three & or more premises \\
  and any number of conclusions & & & & as well \\
\end{tabular}}
\]

Again, \TeX{} is simplistic. Where \TeX{} performs actual typesetting, interpreting \texttt{\&} as horizontal or vertical breaks, \TeX{} always interpret \texttt{\&} as an horizontal break. In fact \TeX{} always interpret all separators (\texttt{\&}, \texttt{\&and}) as horizontal breaks, when they appear in the arguments of the \texttt{infrule} command. Nevertheless prefixing separators with \texttt{\&va} yields vertical breaks:

\begin{verbatim}
\begin{infrule}
  \{aa \&va\& bb\}
  \{dd \& ee \& ff\}
\end{infrule}
\end{verbatim}

The color of the horizontal rule that separates the premises and conclusions can be changed by redefining the command \texttt{\mpr@shline@color}. This color must be specified as a low-level color (cf. Section B.14.2.2).

B.17.15.3 Options

By default, lines are centered in inference rules. However, this can be changed either by using \texttt{\mprset{flushleft}} or \texttt{\mprset{center}}, as shown below.
\verbatimset{flushleft}
\inferrule
\{a \and bbb \hva\and ccc \and dddd\}
\{e \and ff \hva\and gg\}
\verbatimset{flushright}

\begin{tabular}{|c|c|}
\hline
\textbf{key} & \textbf{Effect for value \(v\)} \\
\hline
before & Execute \(v\) before typesetting the rule. Useful for instance to change the maximal width of the rule. \\
left & Put a label \(v\) on the left of the rule. \\
Left & Idem. \\
right & As left, but on the right of the rule. \\
Right & As Left, but on the right of the rule. \\
lab & Put a label \(v\) above the inference rule, in the style of \texttt{\inferrule}. \\
Lab & Idem. \\
vdots & Raise the rule by \(v\) and insert vertical dots, the length argument is translated to a number of line-skips. \\
\hline
\end{tabular}

Additionally, the value-less key center centers premises and conclusions (this is the default), while \texttt{flushleft} commands left alignment of premises and conclusions (as \verbatimset{flushleft} does). Other keys defined by the \LaTeX{} \texttt{mathpartir} package exist and are parsed, but they perform no operation.

As an example, the code
\begin{verbatim}
\begin{mathpar}
\inferrule* [Left=Foo] 
\{\inferrule* [Right=Bar, width=8em, 
leftskip=2em, rightskip=2em, vdots=1.5em] 
\{a \and a \and bb \hva\and cc \and dd\} 
\{ee\} 
\and ff \and gg\} 
\{hh\}
\hva\and
\inferrule* [lab=XX]{uu \and vv}{ww}
\end{mathpar}
\end{verbatim}

77
produces the following output:

\[
\begin{array}{cc}
  & a \quad a \\
  \text{cc} & \text{dd} \\
\end{array}
\]

\[
\begin{array}{cccc}
  a & a & \text{bb} & \text{BAR} \\
  \text{cc} & \text{dd} & \text{XX} & \text{ww} \\
  \text{ee} & ff & \text{gg} & \text{hh} \\
  \text{Foo} & \text{BAR} & uu & vv \\
\end{array}
\]

B.17.16 The \texttt{ifpdf} package

This package should be present in modern \LaTeX\ installations. Basically, the package defines a boolean register \texttt{pdf}, whose value is true for tools that produce PDF (such as \texttt{pdflatex}) and false for tools that produce DVI (such as \texttt{latex}).

The hevea version of the package simply defines the boolean register \texttt{pdf} with initial value true. Command-line option \texttt{-pdf} is also added to \texttt{imagen} command-line options (by using the command \texttt{\addimagenopt}, see Section 10.7). As a result, \texttt{imagen} will normally call \texttt{pdflatex} in place of \texttt{latex}.

In case standard \LaTeX\ processing in \texttt{imagen} is wished, one can issue the command \texttt{\pdffalse} after loading the ifpdf package and before \texttt{\begin{document}}. Then, no command line option is added. Hence, to achieve \LaTeX\ processing of the \texttt{image} file, while still loading the ifpdf package, one writes:

\begin{verbatim}
\usepackage{ifpdf}
\%HEVEA\pdffalse
\end{verbatim}

B.17.17 Typesetting Thai

\texttt{HVVA} features an implementation of Andrew Seagar's technique for Thai in \LaTeX, by the means of the package \texttt{thai.hva} in the distribution.

As regards input encoding, Thai users of \texttt{HVVA} could (perhaps) use \texttt{\usepackage[utf8]{inputenc}}. However, the typesetting of Thai is more subtle than just proper characters. For that reason, Thai in \LaTeX\ is better performed by another technique, which \texttt{HVVA} supports. See this specific document\footnote{http://hevea.inria.fr/doc/thaihevea.html}.

B.17.18 Hanging paragraphs

The \texttt{hanging} package is implemented. \texttt{HVVA} implementation consists of no-ops, except for the \texttt{hangparas} environment, which is partially implemented. Assume the following usage of \texttt{hangparas}:

\begin{verbatim}
\begin{hangparas}{wd}{n} ... \end{hangparas}
\end{verbatim}

where \texttt{wd} is a length that makes sense both for \LaTeX\ and CSS (typically 2ex). Then \texttt{html} output will reproduce \LaTeX\ output for \texttt{n = 1}, regardless of the given value of argument \texttt{n}. That is, in any paragraph inside the environment, all lines except the first get indented by \texttt{wd}.

B.17.19 Other packages

The \texttt{fancyverb} and \texttt{colortbl} packages are partly implemented.

The \texttt{xspace} package is implemented, in simple cases, rendering is satisfactory, but beware: \texttt{HVVA} differs significantly from \TeX, and discrepancies are likely.

The \texttt{chngcnts} package is implemented. This package provides commands to connect (and disconnect) counters once they are created.

The \texttt{import} package is partially implemented: all starred commands are missing.

\footnote{http://hevea.inria.fr/doc/thaihevea.html}
The booktabs package is implemented. This package provides nicer rulers in tables as specific commands. \texttt{\HVEA} defines those as no-ops.

Part C
Practical information

C.1 Usage

C.1.1 \texttt{\HVEA} usage

The \texttt{\HVEA} command has two operating modes, normal mode and filter mode. Operating mode is determined by the nature of the last command-line argument.

C.1.1.1 Command line arguments

The \texttt{\HVEA} command interprets its arguments as names of files and attempts to process them. Given an argument \texttt{filename} there are two cases:

- If \texttt{filename} is \texttt{base.tex} or \texttt{base.hva}, then a single attempt to open \texttt{filename} is made.
- In other cases, a first attempt to open \texttt{filename.tex} is made. In case of failure, a second attempt to open \texttt{filename} is made.

In all attempts, implicit filenames are searched along \texttt{\HVEA} search path, which consist in:

1. the current directory ".",
2. user-specified directories (with the -I command-line option),
3. \texttt{\HVEA} library directory.
4. one of the sub-directories \texttt{html}, \texttt{text} or \texttt{info} from \texttt{\HVEA} library directory, depending upon \texttt{\HVEA} output format.

The \texttt{\HVEA} library directory is fixed at compile-time (this is where \texttt{\HVEA} library files are installed) and typically is \texttt{/usr/local/lib/hevea}. However, this compile-time value can be overridden by setting the \texttt{\HEVEADIR} shell environment variable. In all cases, the value of \texttt{\HVEA} library directory can be accessed from the processed document as the value of the command \texttt{\valueof{\HEVEALIBDIR}}.

C.1.1.2 Normal mode

If the last argument has an extension that is different from .hva or has no extension, then it is interpreted as the name of the main input file. The main input file is the document to be translated and normally contains the \texttt{\documentclass} command. In that case two \texttt{basenames} are defined:

- The input basename, \texttt{basein}, is defined as the main input file name, with extension removed when present.
- The output basename, \texttt{baseout}, is \texttt{basein} with leading directories omitted. However the output basename can be changed, using the -o option (see below).
HEVEA will attempt to load the main input file. Ancillary files from a previous run of \LaTeX{} (i.e. .aux, .bbl and .idx files) will be searched as \texttt{basein.ext}. The output base name governs all files produced by HEVEA. That is, HTML output of HEVEA normally goes to the file \texttt{baseout.html}, while cross-referencing information goes into \texttt{baseout.aux}. Furthermore, if an \texttt{image} file is generated (cf. section 6), its name will be \texttt{baseout.image.tex}.

Thus, in the simple case where the \texttt{hevea} command is invoked as:

\begin{verbatim}
# hevea file.tex
\end{verbatim}

The input basename is \texttt{file} and the output basename also is \texttt{file}. The main input file is searched once along \texttt{hevea} search path as \texttt{file.tex}. HTML output goes into file \texttt{file.html}, in the current directory. In the more complicated case where the \texttt{hevea} command is invoked as:

\begin{verbatim}
# hevea ./dir/file
\end{verbatim}

The input base name is \texttt{./dir/file} and the output basename is \texttt{file}. The main input file is loaded by first attempting to open file \texttt{./dir/file.tex}, then file \texttt{./dir/file}. HTML output goes into file \texttt{file.html}, in the current directory.

Finally, the output base name can be a full path, but you have to use option \texttt{-o}. For instance, we consider:

\begin{verbatim}
# hevea -o out/out.html file.tex
\end{verbatim}

Then, HTML output goes into \texttt{out/out.html} — notice that directory \texttt{out} must exist. Furthermore, \texttt{hevea} output base name is \texttt{out/out}. This means that \texttt{hevea} generates files \texttt{out/out.aux}, \texttt{out/out.image.tex} etc.

The \texttt{article.hva}, \texttt{seminar.hva}, \texttt{book.hva} and \texttt{report.hva} base style files from HEVEA library are special. Only the first base style file is loaded and the \texttt{\documentclass} command has no effect when a base style file is already loaded. This feature allows to override the document base style. Thus, a document \texttt{file.tex} can be translated using the \texttt{article} base style as follows:

\begin{verbatim}
# hevea article.hva file.tex
\end{verbatim}

### C.1.1.3 Filter mode

If there is no command-line argument, or if the last command-line argument has the extension \texttt{.hva}, then there is neither input base name nor output base name, the standard input is read and output normally goes to the standard output. Output starts immediately, without waiting for \texttt{\begin{document}}. In other words \texttt{hevea} acts as a filter.

Please note that this operating mode is just for translating isolated \LaTeX{} constructs. The normal way to translate a full document \texttt{file.tex} being "\texttt{hevea file.tex}" and not "\texttt{hevea < file.tex} > \texttt{file.html}".

### C.1.1.4 Options

The \texttt{hevea} command recognizes the following options:

- \texttt{-version} Show \texttt{hevea} version and exit.
- \texttt{-v} Verbose flag, can be repeated to increase verbosity. However, this is mostly for debug.
- \texttt{-dv} Add border around some of the block-level elements issued. Specifically, all \texttt{DIV} and \texttt{P} are bordered, while the structure of displayed material is also shown.
- \texttt{-s} Suppress warnings.
- \texttt{-l dirname} Add \texttt{dirname} to the search path.
-o name  Make name the output basename. However, if name is base.html, then the output basename is base. Besides, -o - makes HTML output to standard output.

--filename Prevent hevea from loading any file whose name is filename. Note that this option applies to all files, including hevea.hva and base style files.

--fix Iterate HTML until a fixpoint is found. Additionally, images get generated automatically.

--optimize HTML by calling esponja (see section C.1.3).

--exec prog Execute file prog and read the output. The file prog must have execution permission and is searched by following the searching rules of hevea.

--francais Deprecated by babel support. This option issues a warning message.

--help Print version number and a short help message.

The following options control the HTML code produced by hevea. By default, hevea outputs a page encoded in US-ASCII with most symbols rendered as HTML or numerical Unicode entities.

--entities Render symbols by using entities. This is the default.

--textsymbols Render symbols by English text.

--morenties Enable the output of some unfrequent entities. Use this option to target browsers with wide entities support.

--mathml Produces MathML output for equations, very experimental.

--pedantic Be strict in interpreting HTML definition. In particular, this option disable size and color changes inside <PRE>... </PRE>, which are otherwise performed.

The following options select and control alternative output formats (see section 11):

--text Output plain text. Output file extension is .txt.

--info Output info format. Output file extension is .info.

--width Set the line width for text or info output, defaults to 72.

Part A of this document is a tutorial introduction to HTML, while Part B is the reference manual of HTML.

C.1.2 Hacha usage

The hacha command interprets its argument base.html as the name of a HTML source file to cut into pieces.

It also recognizes the following options:

--v Be a little verbose.

--o filename Make Hacha output go into file filename (defaults to index.html). Additionally, if filename is a composite filename, dir/base, then all files outputted by Hacha will reside in directory dir.

--tocbibs Another style for table of contents: sub-tables are replicated at the beginning of every file.

--tociter Like --tocbibs above, except that sub-tables do not appear in the main table of contents (see Section 7.2.3).

--nolinks Do not insert Previous/Up/Next links in generated pages.
-hřf Output a base_hřf file, showing in which output files are the anchors from the input file gone. The format of this summary is one "anchor\tfile" line per anchor. This information may be needed by other tools.

-help Print version number and a short help message.

Section 7 of the user manual explains how to alter HřRA default behavior.

C.1.3 esponja usage

The program esponja is part of HřRA and is designed to optimize havea output. However, esponja can also be used alone to optimize text-level elements in HTML files. Since esponja fails to operate when it detects incorrect HTML, it can be used as a partial HTML validator.

C.1.3.1 Operating modes

With no argument, esponja acts as a filter, it reads the standard input and writes on the standard output. Otherwise, esponja interprets its arguments as names of files and attempt to process them. It is important to notice that esponja will replace files by their optimized versions.

Hence, to optimize file foo.html into foo_opt.html, one should invoke esponja as follows.

# esponja < foo.html > foo_opt.html

By contrast, invoking esponja as

# esponja foo.html

will alter foo.html. Of course, if esponja does not succeed in making foo.html any smaller or if esponja fails, the original foo.html is left unchanged. Note that this feature allows to optimize all HTML files in a given directory by:

# esponja *.html

C.1.3.2 Options

The command esponja recognizes the following options:

- -v Be verbose, can be repeated to increase verbosity.

- -n Do not alter input files. Instead, esponja output for file input goes to file input.esp. Option -n implies option -v.

- -u Output esponja intermediate version of HTML. In most occasions, this amounts to pessimize instead of to optimize. It may yield challenging input for other HTML optimizers.

C.1.4 bibhva usage

The program bibhva is a simple wrapper, which basically forces bibtex into accepting a .haux file as input and producing a .bibbl file as output. Usage is bibhva bibtexas\n options basename.
C.1.5 imagen usage

The command imagen is a simple shell script that translates a \TeX document into many .png images. The imagen script relies on much software to be installed on your computer, see Section C.4.1.

It is a companion program of H\TeX, which must have been previously run as:

```
# hevea... base.tex
or
# hevea... -o base.html...
```

In both cases, base is H\TeX output basename. When told to do so (see section 6) H\TeX echoes part of its input into the base.image.tex file.

The imagen script should then be run as:

```
# imagen base
```

The imagen script produces one basennum.png image file per page in the base.image.tex file.

This is done by first calling \latex on base.image.tex, yielding one dvi file. Then, \dvips translates this file into one single Postscript file that contains all the images, or into one Postscript file per image, depending upon your version of \dvips. Postscript files are interpreted by ghostscript (gs) that outputs ppm images, which are then fed into a series of transformations that change them into .png files.

The imagen script recognizes the following options:

-mag nnnn Change the enlarging ratio that is applied while translating DVI into Postscript. More precisely, \dvips is run with -xnnnn option. Default value for this ration is 1414, this means that, by default, imagen magnifies \TeX output by a factor of 1.141.

-extra command Insert command as an additional stage in imagen ppm to png production chain. command is an Unix filter that expects a ppm image in its standard input and outputs a ppm image on its standard output. A sensible choice for command is one command from the netpbm package, several such commands piped together, or various invocations of the convert command from ImageMagick.

-quant number Add an extra color quantization step in imagen ppm image production chain, where number is the maximal number of colors in the produced images. This option may be needed as a response to a failure in the image production chain. It can also help in limiting image files size.

-png Output PNG images. This is the default.

-gif Output GIF images in place of PNG images. GIF image files have a .gif extension. Note that hevea should have been previously run as hevea gif.hva base.tex (so that the proper .gif filename extension is given to image file references from within the html document).

-pnm Output PPM images. This option mostly serves debugging purposes. Experimented users can also take advantage of it for performing additional image transformation or adopting exotic image formats.

-t any Pass option "-t any" to dvips. For instance, using "-t a3" may help when images are truncated on the right.

-pdf Have imagen call pdflatex instead of latex.

The first three options enable users to control some misbehaviors. For instance, when the document base style is seminar, image orientation may be wrong and the images are too small. This can be cured by invoking imagen as:

```
# imagen -extra "pmnflip -ccw" -mag 2000 base
```

Notice that hevea calls imagen by itself, when given the command-line option -fix. In that situation, the command-line options of imagen can be controled from source file by using the command \@addimagenopt (see Section 10.7).
C.1.6 Invoking hevea, hacha and imagen

In this section, we give a few sequence of (Unix) commands to build the HTML version of a document in various situations. The next section gives a few Makefile's for similar situations.

We translate a file doc.tex that requires a specific style file doc.hva. The file is first translated into doc.html by hevea, which also reads the specific style file doc.hva. Then, hacha cuts doc.html into several, doc001.html, doc002.html, etc. also producing the table of links file index.html.

# hevea -fix doc.hva doc.tex
# hacha doc.html

Thanks to the command-line option -fix, hevea runs the appropriate number of times automatically. In case hevea produces a non-empty doc.image.tex file, then hevea calls imagen by itself (because of option -fix). Hence, the above sequence of two commands is also appropriate in that situation.

In case some problem occurs, it is sometime convenient to run imagen by hand. It is time not to use the option -fix.

# rm -f doc.image.tex
# hevea doc.hva doc.tex

Now, hevea normally has shown the imagen command line that it would have run, if it had been given the option -fix. For instance, if doc.hva includes \input (png.hva), then hevea shows the following warning:

HeVeA Warning: images may have changed, run 'imagen -png doc'

Now, one can run imagen as it should be.

It is sometime convenient not to clobber the source directory with numerous target files. It suffices to instruct hevea and hacha to output files in a specific directory, say doc.

# hevea -fix -o doc/doc.html doc.hva doc.tex
# hacha -o doc/index.html doc/doc.html

Notice that hevea does not create the target directory doc; it must exist before hevea runs. Again, in case hevea calls imagen, image generation should proceed smoothly and the final files doc001.png, doc002.png, ... should go into directory doc.

In all situations, while installing files to their final destination, it is important not to forget any relevant files. In particular, in addition to the root file (index.html), contents files (doc001.html, doc002.html, etc.) and images (doc001.png, doc002.png, etc.), one should not forget the arrow images and the style sheet generated by hacha (content_motif.gif, next_motif.gif, previous_motif.gif and doc.css).

As a consequence, producing all files into the subdirectory doc may be a good idea, since then one easily install all relevant files by copying doc to a public destination.

# cp -r doc $(HOME)/public_html

However, one then also installs the auxiliary files of hevea, and hevea output file doc.html, which is no longer useful once hacha has run. Hence, those should be erased beforehand.

# rm -f doc/doc.h{html,aux,ind,toc} doc/doc.image.tex
# cp -r doc $(HOME)/public_html

C.1.7 Using make

Here is a typical Makefile, which is appropriate when no images are produced.
HEVEA=hevea
HEVEAOPTS=-fix
HACHA=hacha
# document base name
DOC=doc
index.html: $(DOC).html
   $(HACHA) -o index.html $(DOC).html
$(DOC).html: $(DOC).hva $(DOC).tex
   $(HEVEA) $(HEVEAOPTS) $(DOC).hva $(DOC).tex

clean:
   rm -f $(DOC).html $(DOC).h{toc,aux,ind}
   rm -f index.html $(DOC) [0-9] [0-9] [0-9].html $(DOC).css

Note that the clean rule removes all the doc001.html, doc002.html, etc. and doc.css files produced by hacha. Also note that make clean also removes the doc.haux, doc.hind and doc.htoc files, which are HAVA auxiliary files.

When the image file feature is used, one can use the following, extended, Makefile:

HEVEA=hevea
HEVEAOPTS=-fix
HACHA=hacha
# document base name
DOC=doc
index.html: $(DOC).html
   $(HACHA) -o index.html $(DOC).html
$(DOC).html: $(DOC).hva $(DOC).tex
   $(HEVEA) $(HEVEAOPTS) $(DOC).hva $(DOC).tex

clean:
   rm -f $(DOC).html $(DOC).h{toc,aux,ind}
   rm -f index.html $(DOC) [0-9] [0-9] [0-9].html $(DOC).css
   rm -f $(DOC).image.* $(DOC) [0-9] [0-9] [0-9].png *_motif.gif

Observe that the clean rule now also gets rid of doc.image.tex and of the various files produced by imagen.

With the following Makefile, hevea, imagen, hacha all output their files into a specific directory DIR.

HEVEA=hevea
HEVEAOPTS=-fix
HACHA=hacha
# document base name
DOC=doc
DIR=$(HOME)/public_html/$(DOC)
BASE=$(DIR)/$(DOC)

$(DIR)/index.html: $(BASE).html
   $(HACHA) -tocter -o $(DIR)/index.html $(BASE).html
$(BASE).html: $(DOC).hva $(DOC).tex

85
partialclean:
   rm -f $(BASE).h{tml,aux,toc,ind} $(BASE).image.*

clean:
   rm -f $(DIR)/*

The above Makefile directly produces HTML and PNG files into the final directory $(HOME)/public_html/$(DOC). The new partialclean entry erases files that are not useful anymore, once imagen and hacha have performed their tasks.

However, most often, it is more appropriate to build HTML and PNG files in a specific directory, and then to copy them to their final destination.

...

#document base name
DOC=doc
DIR=$(DOC)
BASE=$(DIR)/$(DOC)
INSTALLDIR=$(HOME)/public_html/$(DOC)

... install: partialclean
cp $(DIR)/* $(INSTALLDIR)
...

C.2 Browser configuration

By default, HêvéA does not anymore use the FACE= symbol attribute to the <FONT ...) tag. As a consequence, browser configuration is no longer needed.

HêvéA now extensively outputs Unicode entities. This first means that HêvéA targets modern browsers with decent unicode support, and only those.

In case your browser is recent and that you nevertheless experience display problems on HêvéA-generated pages, see the excellent Alan Wood’s Unicode Resources\(^{11}\). It may help to understand display problems and even to solve them by configuring browsers or installing some fonts.

C.3 Availability

C.3.1 Internet stuff

HêvéA home page is http://hevea.inria.fr/. It contains links to the on-line manual\(^{10}\) and to the distribution\(^{11}\).

The author can be contacted at Luc.Marant@inria.fr.

C.3.2 Law

HêvéA can be freely used and redistributed without modifications. Modifying and redistributing HêvéA implies a few constraints. More precisely, HêvéA is distributed under the terms of the Q Public License,

\(^{9}\)http://www.alanwood.net/unicode/

\(^{10}\)http://hevea.inria.fr/doc/

\(^{11}\)http://hevea.inria.fr/distrib
but \texttt{HAVVA} binaries include the Objective Caml runtime system, which is distributed under the Gnu Library General Public License (LGPL). See the LICENSE\textsuperscript{12} file for details.

The manual itself is distributed under the terms of the Free Document Dissemination Licence\textsuperscript{13}.

\section*{C.4 Installation}

\subsection*{C.4.1 Requirements}

The programs \texttt{havea} and \texttt{hacha} are written in Objective Caml\textsuperscript{14}. Thus, you really need Objective Caml (the more recent version, the better) to compile them. However, some binary distributions exist, which are managed by people other than me (thanks to them). Links to some of these distributions appear in \texttt{HAVVA} home page.

\texttt{HAVVA} users may instruct the program not to process a part of the input (see section 6). Instead, this part is processed into a bitmap file and \texttt{HAVVA} outputs a link to the image file. \LaTeX source is changed into .paj images by the \texttt{imagen} script, which basically calls \texttt{latex}, dvips, ghostscript\textsuperscript{15} and the convert command from the image processing package \texttt{ImageMagick}\textsuperscript{16}.

To benefit from the full functionality of \texttt{HAVVA}, you need all this software. However, \texttt{HAVVA} runs without them, but then you will have to produce images by yourself.

\subsection*{C.4.2 Principles}

The details are given in the \texttt{README} file from the distribution. Basically, \texttt{HAVVA} should be given a library directory. The installation procedure stores the \texttt{havea.hva} and base style files in this directory. There are two compilation modes, the opt mode selects the native code OCaml compiler ocamlc, while the byte mode selects the bytecode OCaml compiler ocamlopt. In \texttt{HAVVA} case, ocamlopt produces code that is up to three times as fast as the one produced by ocamlc. Thus, default compilation mode is opt, however it may be the case on some systems that only ocamlc is available.

Note that, when installing \texttt{HAVVA} from the source distribution, the \texttt{havea.sty} file is simply copied to \texttt{HAVVA} library directory. It remains users responsibility to make it accessible to \LaTeX.

\section*{C.5 Other \LaTeX to html translators}

This short section gives pointers to a few other translators. I performed not extensive testing and make no thorough comparison.

\texttt{LaTeX2Html} \texttt{LaTeX2Html} is a full system. It is written in perl and calls \LaTeX when in trouble. As a consequence, \LaTeX2Html is powerful but it may fail on large documents, for speed and memory reasons. More information on \LaTeX2Html can be found at

\begin{center}
\end{center}

\texttt{TTH} The principle behind TTH is the same as the one of \texttt{HAVVA}: write a fast translator as a lexer, use symbol fonts and tables. However, there are differences, TTH accepts both \LaTeX and \texttt{HAVVA} source. TTH is written in C and the full source is not available (only tex output is available). Additionally, TTH insist on not using any kind of \LaTeX generated information and will show proper cross-reference labels, even when no \texttt{aux} file is present. TTH output is a single document, whereas \texttt{HAVVA} can cut

87
the output of HtMk into several files. (however there exists a commercial version of TTH that provides this extra functionality). TTH can be found at

http://hutchinson.belmont.ma.us/tth/.

htmlgen The htmlgen translator is specialized for producing the Camel manuals. This is HtMk direct ancestor and I owe much to its author, X. Leroy. See [htmlgen] for a description of htmlgen and a (bit outdated) discussion on \LaTeX to HTML translation.

C.6 Acknowledgements

The following people contributed to HtMk development:

- Philip A. Viton, maintains a Windows (win32) port of HtMk.
- Abhishek Thakur implemented most of the new features if version 1.08, including, translations of symbols to Unicode entities, the babel package, and style sheet support.
- Christian Queinnec wrote an extra lexer to translate code snippets produced by its tool VideoC for writing pedagogical documents on programming. The very principle he introduced for interfacing the videoc lexer with HtMk main lexers is now used extensively throughout HtMk source code.
- Andrew Seagar is at the origin of support for the Thai language. He is the author of the document “How to Use HtMk with the Thai Character Set”.
- Pierre Boulet, by using HtMk as a stage in his tool MiDoc for documenting Objective Caml source code, forced me into debugging HtMk implementation of the alitt environment.
- Nicolas Tessaud implemented the -text and -info output modes (see section 11).
- Georges Mariano maintains the hevea mailing list, asked for many feature, and argued a lot to have them implemented.
- Many users contributed by sending bug reports.
